"A.B.C." Audited Circulations

---a requirement for membership in the

BUSINESS NEWSPAPERS ASSOCIATION OF CANADA

ONE of the qualifications that the "B.N.A." of Canada demands of its members is that their circulations claims and methods be verified and audited by the Audit Bureau of Circulations—an organization whose stamp of approval is accepted by advertisers in Canada and the United States.

The A.B.C. in its audit sifts the dross from the gold of circulation. Its methods are scrupulous and it classifies those subscribers who have actually paid for the paper.

Bought and paid-for circulation implies reader interest and reader demand—something that can only be built on sound editorial service. All this means that the sterling mark of "B.N.A." not only confirms the correctness and honesty of circulation claims and methods but also indicates high editorial quality.

The publications below are "B.N.A." members and accept and conform to its rigid demands in business and editorial practice.

Compare the Cost of Upkeep of

D. K. McLAREN'S

Genuine British Oak-Tanned Leather Belting

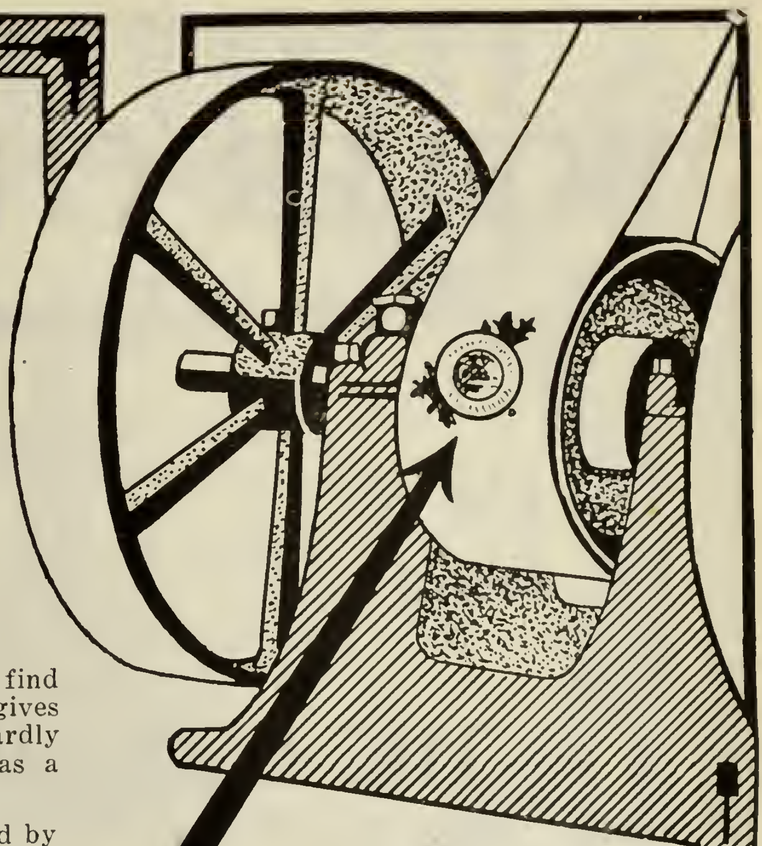
with that of any other make and you will find that D. K. McLaren's Belting not only gives a service that is exceptional—requiring hardly any attention at all—but invariably has a longer life. This is because:

Only the choicest hides, specially selected by experts, are used and, of these, everything but the **tough back portions** is discarded so far as D. K. McLaren's Belting is concerned.

Because every inch is subjected to the Genuine British Oak Tanning Process which has no equal for strengthening the leather and making it flexible.

Because all the stretch is taken out of D. K. McLaren's Belting before it goes into service, so that it maintains a positive grip and can be depended upon to run true at all times.

Ask any user and be convinced



Look for the Oak Leaf

Every length of D. K. McLaren's Leather Belting is stamped with the Oak Leaf. This is your guarantee that you are getting belting that is tanned by the Genuine British Oak Method. It's your guarantee of better service at lower cost.

BOILER CHEMICALS

Made in Canada for You

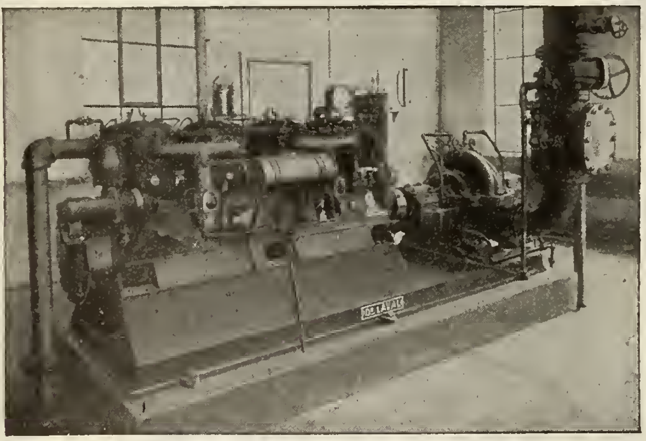
Do it Now

Not a hit-and-miss ready-made compound, but made for you on scientific principles.

Send us ½ gallon sample of the water used in your boiler, together with a description of your boiler plant, for analysis, and be convinced.

THE BIRD-ARCHER CO.

Office: McGill Bldg., Montreal **Factory: Cobourg**



One of two DeLaval centrifugal pumps driven by gasoline engines; installed for the City of Pembroke, Ont.; 900 gal. per min. against 349 ft. head at 1,400 r.p.m.

Gasoline Engine Driven Centrifugal Pumps For Water Works Service

THE high thermal efficiency of internal combustion engines, the small amount of attention required in their operation, and the small building space and light foundations required, recommend them as a most economical drive for pumps under certain conditions, particularly for standby or reserve plants.

The photograph shows one of two De Laval units recently installed for the City of Pembroke, Ontario. In this unit, the numerous pump valves, packings, etc., found in reciprocating pumps, are eliminated, so that attention is rarely required. Such parts as are subject to wear are made on an interchangeable limit-gauge basis, and worn parts can be replaced easily by new parts ordered from the factory. The high efficiency of De Laval pumps results in a marked saving of fuel.

If you will state your pumping requirements fully, our engineers will advise you as to the best type of equipment for your conditions. **Ask for special publication W 100.**

No. 3.—Regina, Sask.

IMPERIAL OIL, LIMITED
SARNIA, ONT., June 9, 1922.

The Goldie & McCulloch Co., Limited,
Galt, Ontario.

Dear Sirs:

I am in receipt of your letter of the 31st ultimo in reference to your Water Tube Boilers which we have installed at our various Refineries, and wish to advise that during the last five years we have installed at our different Plants the following Goldie & McuCloch Type "B" Sectional Water Tube Boilers:

No.	Rated Capacity	Working Pressure	Year Installed
Refinery at Dartmouth, Nova Scotia:			
4	405 H.P.	200 lbs.	1917
4	405 H.P.	200 lbs.	1919
2	405 H.P. fitted with built in Steam Superheaters.	200 lbs.	1921
Refinery at Sarnia, Ontario:			
4	425 H.P.	200 lbs.	1919
2	425 H.P.	200 lbs.	1920
Refinery at Regina, Saskatchewan:			
2	313 H.P., fitted with built in Steam Superheaters	200 lbs.	1920

As to our experience with these Boilers, I am pleased to advise that same have been very satisfactory. We are able to operate them at very high overloads, exceeding at times for quite long periods 200 to 225 per cent. rating. The refractory materials in the furnaces seem to be the limiting factor as far as capacity is concerned. I believe the above, also the fact that our costs for repairs have been negligible, is good proof that the design, material and workmanship are in every way first-class. We are therefore pleased to go on record in stating that the Boilers in every way have been up to our expectations, and our repeat orders as shown above are without doubt our best evidence in this connection.

Yours very truly,

T. MONTGOMERY, Chief Engineer.

TM/K.

Size Up Plant Wastes

TOO many Canadian engineers, especially those in the smaller plants, are overawed by the term "increased efficiency," feeling that it is something mysterious which can only be accomplished by an expert at great expense, or by entirely revamping the existing apparatus.

As a matter of fact, economy merely involves the application of the first principles of engineering, coupled with common sense, for it resolves itself in a nutshell into getting out of the fuel consumed the greatest amount of steam or power possible. While waste is doubtless less in a plant where the operatives take an interest in securing the best results than in a plant loosely run, it is surprising how much either case opens itself to possibilities in the way of savings by a systematic study of conditions. Too often the operating engineer allows himself to become so wrapped up in ordinary routine that he loses his ability to size up the situation as a whole, which is also often the reason why an outside engineer can put into effect all sorts of savings which it is the wonder of the management did not occur to the operating man long ago. Of course, it is fortunately true that striking exceptions to this line of reasoning crop up from time to time, such as the phenomenal savings affected by A. M. Auchterlonie, engineer at the Sick Children's Hospital, Toronto, in the past three or four years.

* * * *

Avoiding Fuel Wastes

MANY engineers, who have studied the principles of combustion, believe that there is much greater waste in the aggregate from chimneys that do not smoke than from those which may be smoking all day long. The most active agent of destruction from chimneys is the sulphur dioxide which eventually, after combination with atmospheric moisture and further oxidation, becomes converted into sulphuric acid.

The comparatively low temperature of the domestic grate is insufficient to prevent sublimation of the sulphur before it reaches the atmosphere, so that most of the sulphur remains in the chimney and an analysis of domestic chimney deposits shows this to be the case.

In the case of the high temperatures associated with industrial chimneys, a much larger proportion of the sulphur finds its way out of the chimney top with correspondingly less deposit in the chimney.

This emission of destructive acid fumes is not dependent primarily upon the amount of smoke given out by chimneys, except so far as the smoke represents unnecessary waste of fuel, but is entirely dependent upon the total amount of fuel burned, wastefully or otherwise. In avoiding smoke, recourse is often made to the use of excess air in unregulated amounts, accompanied by increased consumption of fuel and increased damage to property from the invisible acid sulphur products of combustion.

From long observation and investigation of the subject in question, it can be safely said that fully 80 per cent. of all factory smoke is unnecessary and not in any way essential to the products concerned and that most of the remaining 20 per cent. could be eliminated by additions to the plant equipment and changes in the systems of firing and control.

* * * *

Firemen Not Responsible

WHEN there is a waste of steam anywhere around the plant, why hold the fireman responsible? He has nothing to do with the steam except producing it. Its travel, use and work are entirely beyond his control and usually outside his interest. Neither is he responsible for variations in the loads. He simply has to meet and carry whatever load may come on.

Then, when a carload of indifferent coal is dumped into the bins, why say to him: "Jim, it's hard luck, but here's where your chance to win blows up."

What the fireman should be judged by, all and singular, is strictly the things he is responsible for, whatever his own conduct and work will produce an effect upon, and that alone.

What he is responsible for, and nothing else, is combustion efficiency, because his business is the burning of coal. He is charged solely with the duty of getting the most heat out of his fuel, burning it with the least waste, using the proper thickness of fuel bed and amount of draft, doing his cleaning thoroughly, being efficient in the burning of whatever coal he is supplied with, in the furnace he works with.

It is only the obligation of the plant to give the fireman the best outfit he can, and to maintain it in an efficient condition, for the selfish sake of his own profits.

* * * *

The Universal Verdict

THIS is the day of avoidable wastes. Production costs must be reduced. No matter from what angle one approaches the subject, be it from that of a desire to sell in the markets of the world, that of a need to reduce living costs, or that of a desire to make a greater profit, the answer is that production costs must come down. It is a universal verdict. The result is to be accomplished by better practices and up-to-date equipment.

There must be better designing, better operating practices, better control of material and production processes.

The boiler room is one of the elements and it is a fruitful field to-day in Canada for correct and effective control methods.

* * * *

Take Care in Installation

THE modern power house, designed for economy at the lowest possible first cost, depends on care and accuracy in installation as well as in operation.

A gasket omitted from a vacuum line, rubbish from welding carelessly left in the steam passages of the boiler, or a supposedly flexible steam connection which has been made rigid, may cause needless expense and embarrassment for the engineer at an unexpected time.

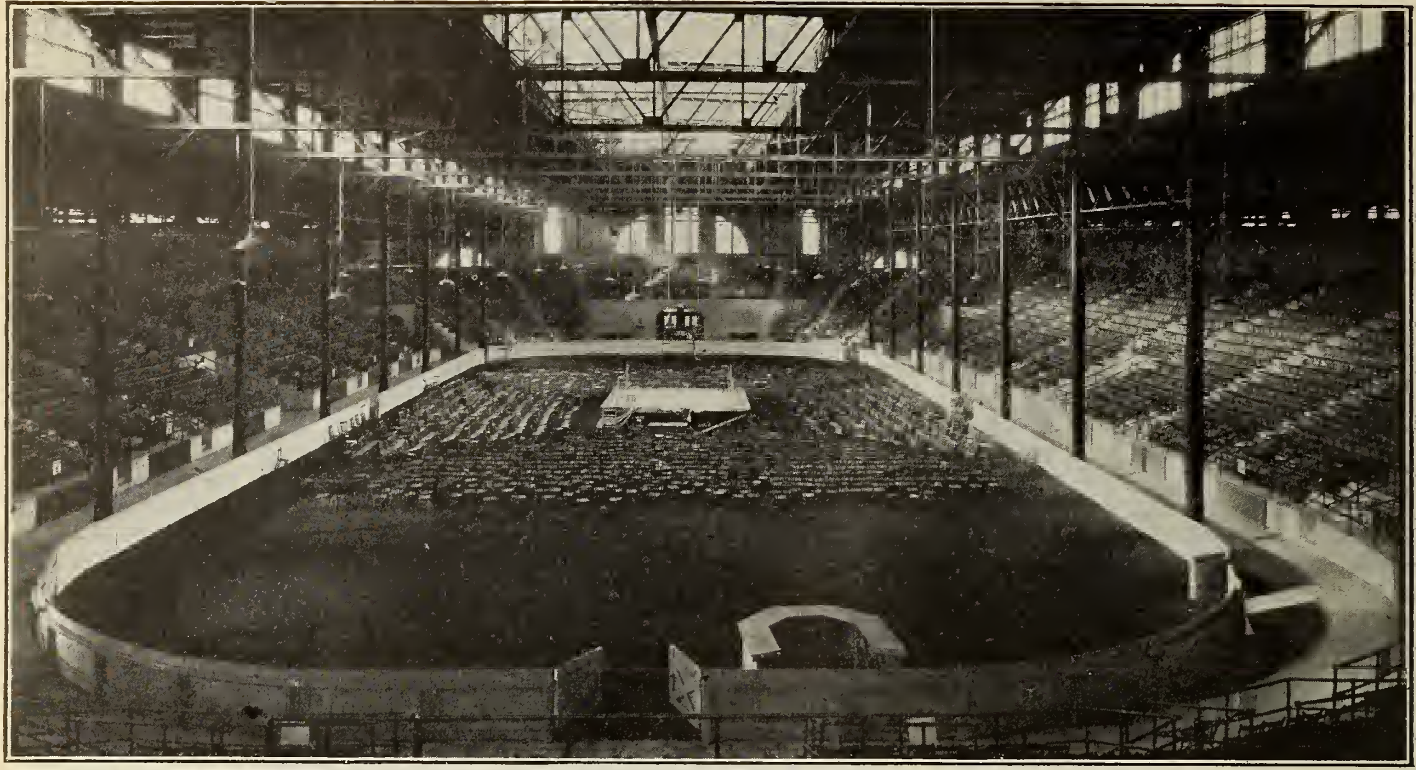

Fig. 2—Interior view of Arena Coliseum, Canadian National Exhibition, Toronto.

Heating Canada's Coliseum With Oil As Fuel

By MELVERN F. THOMAS, M.M.E., Consulting Engineer, 229 College St., Toronto.

A Timely Description of the Problems Peculiar to the Heating of the Huge Arena and Its Annexes on the Eve of the Opening of the Canadian National Exhibition

THE building known as the Coliseum at the Canadian National Exhibition, is 600 feet by 390 feet wide, consisting of a centre section called the Arena, 240 feet by 390 feet, and 54 feet in height on the inside, and the east and west annex buildings, each 180 feet by 338 feet, two stories in height.

The structure is symmetrical about its two main axes, and four towers rising to a height of over 100 feet form the corners of the Arena or centre section.

The walls are constructed of brick, the ground floor of concrete laid on the earth, the terraces for the seats in the Arena and the upper promenade at the rear of reinforced concrete. The second floors of the annex buildings and the entire roof, are constructed of wood supported upon a steel frame.

Figure 1 shows the south front of the Arena and a portion of the annex buildings, and the north elevation has a similar appearance.

Used Throughout Year

The Coliseum is one of the group of buildings in Exhibition Park. It is used throughout the year for many purposes, unlike many of the other buildings which are seldom used except during the Canadian National Exhibition.

In the west annex there is a large, completely equipped kitchen, with dining and lunch rooms, which can be put into service quickly to supply meals to meet any demand.

The large floor areas in the annexes are used each year during Exhibition to house domestic equipment and during the Royal Winter Fair the west section is utilized for similar purposes and for the display of food products, while the east section houses exhibits of birds, fowls, small farm animals and cattle.

Last winter, these sections of the buildings were used for a furniture exhibit, extending over a period of two weeks.

Space for 7,800 Chairs

The arena has an oval, 100 feet wide by 230 feet long, floored with cinders and covered with tan bark. Surrounding this oval, there is a concrete promenade, 12 ft. wide, from which the reinforced concrete terraces rise and furnish space for 7,800 chairs. This section of the building is shown in Figure 2, and has already been used for musical events, grand opera, boxing contests, live stock judging, horse shows, riding and jumping contests and it is proposed to provide at some future time, an artificial ice rink in the oval for hockey games and skating contests.

As the building is intended for service throughout the year, it was necessary to provide artificial heat, and the writer was instructed to design a system which would meet the demand for any of the foregoing services as well as possibly for flower shows. The system also had to be adapted to permit the plant to be closed down during the winter for several weeks, should there be no demand for the building, although at the same time provision had to be made to quickly raise the temperature in one or more sections of the building for an event possibly lasting only one evening.

Used Direct Radiation

The building was completed before the heating plant was designed, and after considerable study of the problem, the writer decided to use direct radiation, divide the building into sections, and install a vacuum steam system arranged so that all of the piping and radiators could be drained clear to the power house.

The quantities entering into the computations for heat losses, were a total volume of 8,000,000 cu. ft., exposed wall surface, 75,000 sq. ft., (13½", 18" and 22½" solid brick without furring), exposed glass in wall, 17,300 sq. ft., single thickness, glass in sky lights, 13,000 sq. ft., single thickness and roof surfaces aggregating 216 000 sq. ft., constructed of wood throughout, covered with roofing felt and the flat surfaces protected by tar and gravel. There is no air space or other insulation to reduce the heat losses from the roof.

Used Temporary System

In the west annex, a heating system consisting of approximately 18,000 sq. ft. of direct radiation and distribution piping had been installed, with a temporary boiler plant, before the system was designed for the old portions of the building. The radiation and piping in this section were not altered, but the temporary boiler plant was removed and new steam mains extended to supply this annex from the new plant.

In the East Annex, 12,000 sq. ft. of direct radiation was installed to replace the heat losses from the exposed wall, glass, sky lights, roof and a small air change, the piping being arranged and valved to control this section of the building in four parts.

This part of the building presented no difficult heating problems, except perhaps estimating the quantity of cold air entering the building, due to infiltration, the opening of doors for stock and constant crowds of people, as well as estimating a surplus heating capacity, necessary to allow the building to be warmed in 4 to 8 hours, after the steam had been off for an extended period.

Problems in Heating

In the centre, or Arena, section of the building, there were several special problems in heating. The large masses of concrete forming the terraces, which are difficult to warm after the heat has been off for several days, the circulation and warming of the large pool of cold air filling the oval, and the difficulty of counteracting the cold current from the roof and sky-light, without placing large coils overhead and inviting a heavy heat loss due to their misuse, as well as the elimination of discomfort from over-heating when the house is crowded, are some of the problems which entered into the design of the heating system.

By distributing a small amount of radiation over the terraces under the seats, the "chilly" effect of the cold concrete was counteracted, and by concentrating radiation at the foot of the terraces and in the passage ways, allowing the air from the centre section to circulate by opening the gates in the close wooden barrier surrounding the oval, it was found possible to temper the larger volume of air in a few hours, even after the building had been out of service for several weeks.

Below Concrete Work

Figure 3 shows the arrangement of the radiation in this section of the building. The entrances and offices at the north and south ends of the Arena are all heated, but this radiation is not shown, as these spaces are below the concrete terrace work.

The total radiation in this section of the buildings is approximately 18,000 sq. ft.

The radiation under the seats consists of a single run of 2" pipe supported in small C. L. pedestals behind each row, each group of terraces being operated as a single radiating unit. A detail on Figure 4 shows the arrangement of the piping for this terrace heating surface, and Figure 3 shows that there are 36 of these groups.

When there is an event requiring the oval to be used as seating space, it will probably be found difficult to prevent some cold draughts in the centre section should the weather be extremely cold and windy.

The entire heating system has been successfully controlled, by having a trained attendant constantly passing through the different sections of the building and operating the valves on the different sections of the mains and the radiator valves on the masses of radiation at the foot of the terraces and on the high level at the rear of the seats. There are four mains, each supplying one quarter of the Arena section, and these are controlled by valves which can be conveniently operated by chains from the ground floor level.

During evening performances, when the house is crowded, it is found desirable to anticipate the possible overheating, and cut off practically all of the radiation immediately after the audience has assembled and then to gradually turn on the necessary heat to keep the building from becoming chilly.

The heating in the Arena could probably have been controlled by automatic thermostats, if funds had been available for a complete installation, although it would have been found difficult to locate the thermostats so as to control the different sections of the building at the proper time to prevent draughts or over-heating.

Steam Plant

A brick power house building, 46 ft. by 64 ft., with brick chimney, is located 20 feet from the east corner of the Coliseum. This building has a boiler room, pump room and in addition a room for housing the electric transformers for this section of the park.

The following steam generating and auxiliary equipment was installed.

Four 72" by 18' 0" H.R.T. Boilers, constructed for 125 lbs. working steam pressure.
Four sets oil burners and furnaces.
One 5' 0" by 5' 0" smoke breeching, constructed of No. 10 gauge steel.
One 7" by 4½" by 8" duplex heavy duty boiler feed pump.

Fig. 5—Plan and section showing arrangement of equipment in Power House.

Fig. 1—Exterior View of Coliseum.

One "Westco" Boiler Feed Pump, direct connected to a 10 horse power electric motor.

This pump has a capacity of 40 Imperial gallons of water per minute against 150 lbs. pressure, and is controlled by a push button operated contactor.

One 10" by 12" by 12" steam operated vacuum pump.

One 65,000 sq. ft. capacity Jennings electric motor driven vacuum pump.

One 8" by 6" by 8" duplex general service oil pump.

This pump is used to draw oil from the tank cars in cold weather and to transfer oil from one tank to another when desired, and the piping is also arranged so that it can be used to supply the oil burners, should the other units be out of service.

One Albany oil pump with direct connected motor to supply burners.

One small duplex steam driven oil pump to supply burners.

One Sturtevant positive air blower, operated by motor to supply air under pressure for starting the oil burners when there is no steam pressure.

General Arrangements

The general arrangement of the equipment is shown on Fig. 5, except that the oil pumping and distribution appartus is not shown.

The plant was designed to allow one reserve boiler, where all the heating system is in operation, and to have duplicate pumping and auxiliary equipment.

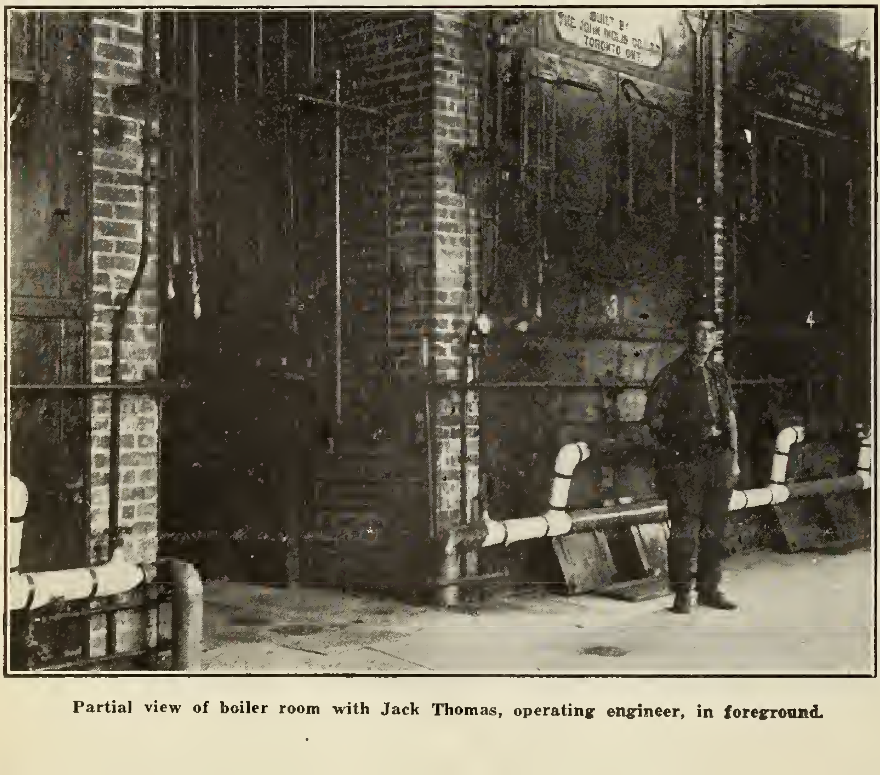
Oil as a fuel was selected, because of its convenience, small amount of labor, quick starting and stopping, easy regulation, and convenient storage underground, where it does not detract from the appearance of the park.

Four cylindrical steel tanks, having a total capacity of 48,000 Imperial gallons, were placed underground near the power house and piped so that oil from tank cars on the siding, 300 feet away, flows by gravity to the storage tanks, or if the oil is slow in running in cold weather, the large service pump is used to empty the tank car.

A system of piping from the tanks to the pump room allows oil to be transferred from one tank to another and to be supplied to the burners from any one of the tanks.

Two Cunerty Burners

The oil burning equipment consists of two Cunerty air or steam atomizing burners in each furnace. These burners operate satisfactorily with an air pressure of 3 to 5 lbs. per sq. in., or with low pressure steam. At this plant the air is used as a means of bringing up the steam pressure on one boiler, after which steam at a reduced pressure of 15 lbs. is supplied to the burner and there further throttled to give the desired rate of combustion.



Partial view of boiler room with Jack Thomas, operating engineer, in foreground.

An important feature of the oil burning furnace in this plant is a fire brick grate through which the air to support combustion is allowed to pass. This, however, is not necessary to prevent smoke, as it was found possible to obtain a perfectly clear flame immediately when starting the burners in a cold furnace. The oil burning equipment has proven satisfactory, and can be easily regulated by using one burner to give less than 25 per cent. of the capacity of the boiler, or by using both burners to exceed the over-load capacity of the boilers and force the water out through the steam piping.

Distribution System

The boilers are operated at 75 to 100 lbs. gauge pressure.

The power house steam piping consists of the ordinary layout of a main header, connected to each boiler with a double system of valves, all of extra heavy material. To the header are connected branches to the various services. There is a small amount of steam distribution to the milk testing building and to four barns. These have separate pressure reducing valves and connections.

The main steam supply for the Arena and annex buildings passes through a primary pressure reducing valve, and is delivered to the mains at a pressure of 5 to 20 lbs., as is necessary to supply the demand.

The pipes pass underground through steel casings covered with concrete, from the power house to the east annex building where they enter a tunnel which extends 496 ft. under the east annex and Arena building.

Branch mains rise from this tunnel and extend to four main distribution points in the east annex and Arena, and from the end of the main, a main rises to serve the old heating system in the West Annex. At the distribution points, secondary pressure reducing valves are installed and the pressure of the steam reduced to 1 to 5 lbs. as is required to supply its demand under any given existing load condition.

The low pressure steam is distributed around the ground floor ceiling, and at each distribution point there are three main valves fitted with sprocket wheels and chains so that they may be conveniently operated from the floor.

The distribution system to the radiation is in accordance with ordinary standard practice for a vacuum heating system, arranged generally so that the condensation will flow in the same direction as the steam to definitely determined drip points.

Each radiator and drip point in the piping is controlled by a thermostatic trap and the drips from the medium and high pressure piping are generally controlled by bucket type traps.

By-Pass Saves Time

It was found that too much time was required to clear the underground main through an ordinary trap when the system was being started up quickly, so to allow the large volume of condensation and air to pass quickly into the return piping, a 2 in. by-pass was provided to be operated by an attendant, who "stands by" until the main is clear, when steam is to be turned on quickly.

Of course, under ordinary conditions, the steam would be turned on to the main slowly, and time allowed for the vacuum pump to clear the system through the drip traps.

Of the radiation return piping, 2.800 ft. is locted in tar-coated wood boxes below the concrete floor. All of this piping is supported on rollers, clear of the enclosing boxes, and is extra heavy, genuine wrought iron. The main return pipe is located in the pipe tunnel and passes through a steel-lined pit in the pump room, where it is connected to the vacuum pumps. The vacuum pumps discharge into a large receiving tank located overhead, and from this tank water flows to the boiler feed pumps. When the steam vacuum and boiler feed pumps are in operation, the exhaust steam from them passes through a coil submerged in the receiving tank, where practically all of it is condensed and reclaimed.

The total radiation in the Arena and two annex buildings, is approximately 48.000 sq. ft., to which must be added about 10 per cent. for uncovered and partially covered piping included in the computations as a part of the heating system. In addition to this load, there is about 2,500 sq. ft. of direct radiation in the barns and milk testing building, and during the Royal Winter Fair. there is a heavy load for heating water and for washing stock.

A Rush Job

The writer was instructed on July 14. 1922, to prepare plans. Contractors had access to the plans on August 3, 1922, and submitted tenders on Aug. 10. The contract was at once awarded to Purdy-Mansell Ltd., under an agreement that the system should be ready to operate for the Royal Winter Fair on Nov. 22 of the same year.

That the work could be planned and installed. and put into operation within such a brief period of time, was due in large measure to the constant co-operation between the Parks Department, representing the City of Toronto as owners, the contractor, and the engineer.

Power Notes

A. B. Stewart, Town Clerk of Estevan, Sask., will soon be calling for tenders in connection with a $22,000 electric lighting plant.

The Imperial Oil, Ltd., 56 Church St., Toronto, is preparing plans for the construction of steel storage oil tanks and pumps in Oshawa, Ont.

The Florence Mining Co., Ltd., Ainsworth, B.C., are calling for tenders for the erection of a $175,000 electric power plant. No closing date has been set.

The Dorin Construction Co., Ltd., 104 Sparks St., Ottawa, have been awarded the contract for the $30,000 water power plant to be built at Buckingham. Que.

The Ottawa River Power Co. Ltd., 145 St. James St., Montreal, Que., is in the market for extensive development equipment, including transmission and power machinery.

The Hydro Electric Power Commission is beginning work on the construction of twenty miles of new lines in London Township, Ont. The estimated cost of the project is about $40,000.

The Hamilton Hydro-Electric Commission are having plans prepared for a $45,000 sub-station on Hamilton St. N. Hamilton. B. H. Prack, 1 Main St. E.. Hamilton, is the architect.

The Haileybury Town Council is planning to install pumping equipment, including stage motor driven centrifugal pumps, for fire protection. The estimated cost of this work is $20 000.

The Northern Ontario Light & Power Co. is now doubling the power supply to Kirkland Lake. The present line, which will be paralleled in part by the new transmission line, is stated to be good for 5,000 h.p.

R. Morrissette, Three Rivers, Que., is in the market for a centrifugal pump, 2½ in. discharge, capacity 125 gallons per minute, and one electric motor. 5 h.p., automatically controlled by the level in the reservoir, 250 ft. from the pumping plant.

At the annual convention of the Association of Electragists (International) held in Vancouver. W. G. Murrin was chairman of the "Electrical" banquet. The principal speakers were Lawrence W. Davis. director of promotion and development in the Association, and Jas. R. Strong, W. Small. W. W. Fraser and others well known in the electrical world.

Installations of a Leonard fire box boiler was made in the North Huron School, Toronto, by John Ritchie Co., Toronto.

John Inglis & Co., Ltd., 14 Strachan Ave., Toronto, are contemplating the installation of an electric travelling crane, sand mixing machine, etc.

The Ford Motor Co. of Canada, Ltd. Ford City, Ont., have under construction a new power and screen house. These are being erected at a cost of $300,000.

The Leonard tubular boilers have been installed in the Leslie St. school, Toronto, through the Arthur S. Leitch Co., Kent Building, Toronto, by B. J. Miller, contractor.

The Arthur S. Leitch Co., Kent Building, Toronto, have supplied the Provincial Paper Mills, at Mille Roche, Ont., with a Jennings exhaust vacuum unit as manufactured by the Nash Engineering Co., together with twenty Armstrong steam traps.

The Chairman, Board of Control, City Hall, Toronto, will receive tenders up to Tuesday, October 9, 1923, for an 80-million-gallon centrifugal pump, 25-million-gallon pumping engine, generator, supply of cast iron pipes, stop valves, and special castings.

The Purdy-Mansell Co., 63 Albert St., Toronto, contractors for the Coco-Cola Company's new building, will equip it with a size "C" Jennings duplex hytor-vacuum heating pump and a Sim's storage heater, through Arthur S. Leitch Co., Kent Building, Toronto.

Laclede-Christy, of St. Louis. have issued a new bulletin describing the Stowe Stoker, which in principle is a combination of the underfeed and the chain grate, the distinctive features being the stationary tuyeres alternating with moving chairs; and a fuel retarding assembly at the ash discharge

Following the visit of Lawford Grant, Montreal, managing director of the Eugene Phillips Electrical Works, Ltd., to Brockville, Ont., it has been announced that work on the construction of the second unit of the company will be proceeded with shortly. The first unit of the company's plant, which is to be removed from Montreal, was erected last year in the form of a rod-rolling mill.

Representatives of the Calgary Power Co. have been in Edmonton conferring with the Edmonton City Council with reference to the furnishing of a supply of electric power. The Calgary Power Co. has a plant on the Bow river, just west of Calgary. and this plan would necessitate the construction of a power line from Calgary to Edmonton, a distance of 196 miles. Changes and improvements would be necessary in the power plant, but if a market for the power can be found in Edmonton they are prepared to make the expenditures.

Toronto No. 1, C.A.S.E. On Frolic at Kew Beach

A Hundred Members With Their Families Enjoy Ball Game "Full o' Pep" as a Fitting Conclusion to Keenly Contested Race Program

MANY members of the Canadian Association of Stationary Engineers were unable to attend the picnic on Thursday, June 28, at Exhibition Park, Toronto, which brought to a close the thirty-fourth annual convention of the association. For this reason, those who did not attend the first picnic, and many who did, met at Kew Beach on Saturday afternoon, August 11, and spent the afternoon in the usual manner of "picknickers."

There were well over a hundred members with their families and friends present, and it is certainly superfluous to comment on the enjoyment shared in by all, for it was very evident. The weather man played his part, and everyone was in the best of spirits, having left dull care behind.

The usual races were run, though perhaps there was more energy and "vim" displayed than usual, due to the interest shown in reaching goal first, and determination not to be left behind brought success to many.

And the children! Did anyone ever see a livelier crowd with such tireless spirits? Races, why they'd have run them from noon till dark without a let-up, and then have been quite ready for more, though it is very doubtful if they would have allowed the supper hour to pass by unnoticed, for certainly none of them forgot to enquire carefully time and again about the hour and whereabouts of the "tea." And they certainly did justice to it, sandwiches, cake, fruit and other refreshments making a rapid disappearance, and keeping the committee and helpers busy.' Yet it wasn't surprising that their appetites seemed larger than usual, for the spot chosen, right by the lake, and the exercise they had had all afternoon, for racing or not they were never quiet, was certainly conducive to hunger, apart from the fact that the viands themselves were most appetizing.

Smokers Are Happy

Every smoker present was given a package of Honeysuckle tobacco and a Bachelor cigar, so they were quite happy. W. M. Ismond. the Toronto factory representative of G. F. Sterne & Sons, Brantford, dispensed orangeade to the thirsty, and was kept busy.

The ball game was "full o' pep," and we expect the professional Toronto team to be making bids for some of the participants. The teams, however. did not seem to be evenly divided as the score of 24-11 proves but the spectators enjoyed the game from the first inning to the last. and heavy hitting was a feature from beginning to end.

The line-up of the teams was as follows:—

Winners—Thompson, c.; Mosely, p.; Burgess, 1b.; Stevens, lf.; Murphy, 2b.; Armstrong, 3b.; Holt, cf.; Quinlan, ss.; Ivers, rf.

Losers—Truelove, c.; Wright, p.; Burgess, 1b.; Brown, 2b.; Dunton, 3b.; Thomas, ss.; McLaren and Giles, rf.; Paton, lf.; Scarfe, cf.

Umpire—George J. Soucy.

The following are some of the races and their winners:—

Girls, 7-12—1, Violet Harvey; 2, Florence Harvey.

Boys, 7-12—1, Willie Glockling; 2, George Brown.

Girls, 12-15—1, Hazel Scharf; 2, Muriel Harvey.

Boys, 12-15—1, Harry Harvey; 2, Willie Glockling.

Girls, 15-18—1, Phyllis Brodie; 2, Jennie Stevens.

Men's Guessing Contest—1, W. Truelove; 2, J. Quinlan.

Engineer's wives balloon race—1, Mrs. E. Wright.

Among those present were John Thompson, of the Dearborn Chemical Co., immediate past president of the Supplymen's Association; C. B. Turner, past president of the Exhibition Committee; R. McLaren, president Toronto No. 1 and vice-president Grand Lodge C.A.S.E.; W. A. Truelove, I.P.P., Toronto No. 1; L. W. Thomas, D.K., Toronto No. 1; Mrs. Mosely, whose husband, the late Charles Mosely, was Grand President of the Grand Lodge and chairman of the Engineer's Examining Board; also Mr. Mosely, Jr., a prominent engineer; Mr. Blackgrove, past grand secretary of the C.A.S.E.; A. Lamoreaux, an honorary member of Toronto No. 1 (who incidentally ran in the race with the 12-year olds, although over 80 years of age); G. A. Brown, recording secretary of Toronto No. 1; Ed. Golightly, vice-president Toronto No. 1; Geo. D. Fowler, one of the trustees of Toronto No. 1, and past president of London No. 30; W. G. Blackgrove, past grand president, and Geo. J. Soucy.

OFFICERS, TORONTO NO. 1, C.A.S.E.
G. J. Soucy, Grand Lodge Secretary; E. Golightly, vice-president; W. A. Truelove, I.PP.; R. McLaren. president; G A. Brown, secretary; John Quinlan, conductor.

Hamilton Council No. 60 U.C.C. Stages Frolic

By N. C. SHATFORD

Thunder and Rain Fail to Mar Festivities at Black's Grove, Ancaster, on August 11—Unusual Prizes Donated Provoke Keen Contests in Sports Events

Left to Right:—P. R. Laver, M. L. Miller, G. R. Brown, S. E. Cosford, Alex. C. Leckie, (Worthy Chief), Wm. Pattison, Bert Stephenson, George Dennison, W. A. Sweet, L. J. Cudbird (Toronto Council) R. B. Hornby, H. McLaren.

THAT members of Hamilton Council, No. 60, Universal Craftsmen Council of Engineers, were disappointed in the weather on the occasion of their annual picnic at Black's Grove, Ancaster, on August 11, is expressing their feelings in mild terms, for after bright sunshine had presaged an ideal day for just such an outing, thunder made itself heard and rain fell in a determined manner.

To a casual observer it certainly did not seem to worry the children a great deal that they had to remain in the grandstand for most of the afternoon, though the liberality of S. E. Cosford in handling the candy, ice cream, and soft drinks may have played a large part in keeping them from becoming restless.

Young George Crosswell kept track of the cones carefully "put away" by Archie Leckie, but George himself had no room for repartee when an interested grown-up remarked it would be impossible for him to compete in the races. However, George showed them what he could do, and won the very first race.

About 4.30 p.m. the rain decided that it had had its innings, and proceeded to clear the track for action. Mr. Cosford, armed with a megaphone, took up the task of letting everyone know where to start, and how, and with the aid of members of the committee, duly placed the eager contestants in line in the various positions adopted for getting up the most speed in the least possible time, and then they were off—some arriving first, some second, and some—well, while they may have come in a little behind time, they did their best.

A unique feature of the prizes was the fact that all were donated by the following firms and individuals:—Robt. Fitzsimmons Co., Ferry Coal Co., Crescent Oil Co., Electric Supply Co., Wood, Alexander & James Co., Barton Electric Works, Canadian Westinghouse, Crane Co. Ltd., H. W. Petrie Co., Chadwick, Carroll Co., Tallman Brass Co., McPherson Shoe Co., Milqo Co., Woodward Chemical Co., Garlock Packing Co., Power House, Duff & Son, Gordon Thomson, Ltd., Standard Sanitary Co., Mark's & Co., Wilkinson & Kompass Co., Kent, Garvin Co., S. E. Cosford, and Metal Studios Co.

Left to right, back row:—Archie Leckie, Jim Leckie, William Pattison, Eddie Lee. Second row—Dorothy Paddock, Marjorie Brown, Kenneth Bull, George Crosswell, Rosalie Leckie, Peggy Lvaer, Kathleen Lee. Third row:—Norma Leckie, Jack Miller, Kathleen Bull, Raymond Bradley, Kathleen Laver, Robert Smith. Front row:—Lois McLarn, Murray Brown, Trafina Parklow.

The entertainment committee consisted of Bert Stephenson, general chairman; S. E. Cosford, chairman, sports committee; and H. Hornby, chairman, refreshment committtee.

The following is the list of races and winners:

Children's Race—1, George Crosswell; 2, Norma Leckie; 3, Edward lee.

Girls' Race, 8 to 10 years—1, Peggy Laver; 2, Rosalie Leckie.

Boys' Race, 8 to 10 years—1, Wm. Pattison; 2, Kenneth Bull.

Girls' Race, 17 years and under—1, Jean Barkley; 2, Frances Beattie.

Boys' Race, 10 to 15 years—1, Jim Leckie; 2, Archie Leckie.

Single Ladies' Race—1, Geraldine Cosford; 2. Jean Barkley.

Wives of Council—1, Mrs. D. R. Laver; 2, Mrs. M. Miller.

Members of Council—1, M. L. Miller; 2, J. McLaren.

Fat Engineers' Race—1, John Grimes; 2, Wm. Pattison.

Wheelbarrow Race (changed to running)—1, Tom Brown; 2, E. Campbell; 3, Bert Stephenson; 4, R. Bradley .

Smoking Race, lady and gentleman—1, Mrs. Leckie & Mr. R. Gill; 2, Mr. & Mrs. J .G. Wilson.

Among the special feature races were the following:

Boot & Shoe Race—1, E. Campbell; 2, D. R. Laver.

Married Ladies—1. Mrs. Cudbird (Toronto); 2, Mrs. Partlow.

Officers Race—1, M. L. Miller; 2, Bert Stephenson.

Boys under 17—1, Jim Leckie; 2, Archie Leckie.

Cake Contest—1. Mrs. Cosford. Tied for 2nd—Mrs. Pattison, Mrs. Laver, Mrs. Knowles.

Averting Loss in Ammonia Compressor Operation

*By S. F. SMITH

A Discussion of the Conditions Controlling the Losses in the Machine with Suggestions for Their Solution in Canadian Plants

IN DISCUSSING the economy of ammonia compressors the term volumetric efficiency is freely used, usually implying the overall efficiency of the ammonia compressor. Engineers and manufacturers frequently quote values which are far apart. This is due to the fact that no specified statement is made of the losses involved, or conditions under which the gases enter and leave the compressor. In this article, the writer has endeavored to point out the losses as they occur, and the conditions which control same. The information given is not new to the engineer, but it is believed the emphasis placed on these points in their proper place will be of some value in the economical operation of Canadian plants.

The losses which occur in the compression machine are as follows:

1. Clearance or re-expansion loss.
2. Pressure loss through suction valves.
3. Loss due to superheating of gas from cylinder walls.
4. Loss due to superheat in suction-gas.
5. Loss due to ammonia liquor entrained in suction gas.

The first two losses are controlled by the design of the compressor and valves; the remaining three losses may be controlled from sources outside of the compressor machine. There is, in addition to the losses at the compressor, an inherent loss of refrigeration, which is the cooling of the ammonia liquor from the temperature at which it leaves the condensers to the temperature at which same evaporates in the refrigerating coils. The loss, even though inherent, may be somewhat reduced.

Basis of Discussion

As a basis of discussion we will take the set of compressor operating conditions as follows:

Absolute suction pressure, 29.7 pounds.
Absolute condenser pressure, 199.7 pounds.
Double-acting compressor.
Adiabatic expansion.
Heat content of suction vapor 537 B.t.u.
Total heat of compression, 123 B.t.u.
Heat content of gas after compression, 660 B.t.u.
Net refrigeration effect per pound of ammonia, 504 B.t.u.

The first loss stated as a result of re-expansion of the high pressure gas which remains in the clearance space of the discharge head of the valve manifold, is apparent from indicator diagrams. Under the conditions of the example taken it will be found that this loss will not exceed five per cent. in the case of double-acting compressors; the suction and discharge pressure corresponding to the example stated.

The total displacement of the compressor, less the re-expansion loss is usually called the apparent volumetric efficiency. This re-expansion loss will be increased at least 15 to 20 per cent. in the case of operating with wet compression.

Wet Compression

By wet compression we refer to a nearly saturated discharge gas having a temperature of around 95 degrees. Careful laboratory tests have been made by numerable ammonia compressor companies, and it is found that where the wet gas is carefully controlled that there will be a difference of about 15 per cent. in this loss. In a plant where machines are operated by this method it is apparent that the loss will be greater as laboratory manipulation cannot be accomplished. Tests have been made to show that with a suction pressure of 31 pounds absolute, and condenser pressure of 200 pounds absolute, that there was an overall loss by the wet compression system of 27 per cent. as compared to dry compression. This may easily be conceived when diagrams are taken from indicator cards operating on the wet compression system.

The second loss is that resulting from the drop in pressure through the suction valve and manifold, same to be governed by the design of the compressor valves. We find to-day that manufacturers usually are furnishing more liberal areas in the suction valves and that the loss is greatly reduced so that same is almost negligible. It would not be uncommon to find a pressure drop of 1½ pounds. Loss resulting from this drop would be in the vicinity of 4 per cent.

A Definite Loss

It will be apparent that the pressure drop is a definite loss, inasmuch as additional work will be required to compress from the pressure, and the capacity of the machine correspondingly reduced.

To effect an equivalent production of refrigeration it is evident that a given machine will have to be correspondingly increased in speed to overcome this loss, as the ammonia pressure at the refrigerating coil is designated to a point where no additional reduction in pressure or increase of volume produces any more effective refrigeration. A similar loss would occur in the case of the installation of a small suction line from the cooler to the machine.

The third loss mentioned, resulting from superheating of the suction as by the cylinder walls, is a loss which is seldom mentioned and referred to. Careful analysis shows that even with the operation of water jackets on ammonia compressors the total loss due to radiation and water jackets is only 30 per cent. of the heat given up by the cylinder walls directly to the ammonia gas in the cylinders. These tests show that the loss resulting from the superheating of the gas by the cylinder wall ranges from 13½ to 22.7 per cent., according to difference in temperatures corresponding to discharge and suction pressures with dry compression.

Controlling Factor

The conditions which control this loss apparently are temperatures corresponding to suction and discharge pressures. Inasmuch as no control can be made of the suction gases, the only place for correction will be in the discharge pressures and volume handled. This is a field which has been entered by the manufacturers of multi-stage compressors. The big loss which is reduced by the various types of compressors is the elimination of some of the superheat, and the lowering of the condenser pressures.

In the case of the two-stage ammonia compressor, the discharge leaving the low-pressure cylinder is cooled to a saturated condition by means of the injection of ammonia liquor through an expansion valve. This, on the surface, would appear as lifting one's self by the boot straps. However, power required to produce refrigeration is governed principally by volume and pressures, irrespective of weight of gas handled. Accordingly it will be apparent that a given volume of superheated gas will result in a smaller value if a given weight of ammonia liquor is expanded into same.

Tests were made three years ago in a two-stage compressor, and it was found that ammonia liquor was expanded into intermediate receiver between the two cylinders, and that the ammonia discharge temperature was 144 degrees with a condenser pressure of 105 pounds gauge. With the same operating conditions and the expansion of ammonia omitted from the intermediate receiver, the temperature of the discharge went to 184 degrees.

It is apparent that the heat of compression resulting from the changed

---

*Testing Engineer, Armour & Co. An address before the Mountain States Ice Manufacturers Association.

operating conditions was greatly increased, as the discharge temperature was steadily on the rise, and it was found unsafe to continue to operate this machine in this manner, and it was found necessary to start the operation of the ammonia liquor expansion valve cooling the liquid in the intermediate receiver.

May Increase Saving

These tests indicated that there was a saving of about 12½ per cent. as compared to ordinary single-stage operation, whereas theoretically saving should be 14 to 15 per cent.

The two-stage compressor no doubt has a good field for low-pressure work. The writer, however, would emphasize the saving effected in the proper use of ammonia liquor expanded into suction side of single-stage compressor, as the liquor injected into the suction-side of the machine will remove some of the superheat resulting from compression, thereby increasing the capacity of the machine and the effected tons of refrigeration produced, which will mean a net saving in tons of coal per ton of refrigeration. It is difficult to specifically state how much ammonia should be added, but a line may be had on same by watching the reduction of ammonia discharge temperature, as in the test referred to the discharge temperature was reduced from 180 degrees to 144 degrees when the ammonia liquor was used for cooling the suction gas. The entire loss cannot be reduced as effectively in a single-stage machine, but a large part of this loss can be recovered.

Relative to the fourth loss. As previously mentioned, the increasing volume of ammonia leaving the refrigerator coils performs no effective work, and, therefore, proper insulation must at all times be provided on suction lines, so that there will be no superheating of the gas from the return system. In the example stated there will be a loss of 1.2 per cent. resulting from a superheat of 3 degrees F. on the suction line. Should a 20 degree superheat exist on the suction line of the example mentioned, there will be a loss of 5.8 per cent.

Relative to the fifth loss. Inasmuch as this loss may be a variable quantity depending on how much liquor is carried back to the compressors, no specified value can be mentioned. There can be no argument against the removal of heavily entrained ammonia. The installation of accumulator trap will no doubt remove all such conditions in the various plants where this condition would exist.

Summarizing the losses as mentioned in the example there will be a total loss of 32.7 per cent., making the net overall efficiency 67.3 per cent., which corresponds very closely with tests made by numerous manufacturers which indicate efficiency of about 70 per cent. for the conditions mentioned.

Tabulation of value of losses existing in example mentioned:

Clearance loss	5.0%
Suction valve loss	4.0%
Compression loss	22.5%
Suction superheat loss	1.2%
Total loss	32.7%
Net comparison efficiency	67.3%

As already mentioned the inherent loss in cooling the ammonia liquor from the temperature at the condenser to the temperature in the cooler will be in the vicinity of 12 degrees for back-pressure of about 5 pounds gauge. In the case of low back-pressure, it is apparent that the cooling of the liquor from the temperature corresponding to the condenser pressure to the temperature corresponding to a 20-lb. back pressure could be effected by means of high pressure suction gas passed directly to high back-pressure machines as the h.p. per ton will be less for the ammonia compressors operating from a high back-pressure to a given condenser pressure than from a low back-pressure to the given condenser pressure.

In other words, about 50 per cent. of the cooling of the liquor in the case of freezer operating may be effected more economically by cooling the liquor by means of high-pressure suction gas, leaving only the balance of the liquor cooling to be performed at the lower back-pressure in the freezer refrigerating coils.

U.C.C. of E. Notes

At the twenty-first international convention of the Universal Craftsmen Council of Engineers, held at the Powers Hotel, Rochester, N. Y., from August 6 to 10, the following officers were elected for the ensuing year: Grand Worthy Chief, George G. Brown, Pittsburgh; Assistant Chief, W. W. Law, Princeton, N.J.; Grand Secretary, Theodore Jones, Washington, D.C.; Grand Treasurer, John L. O'Brien, Chicago; Warden, Walter Damen, Springfield, Mass.: Grand Guard, Louis J. Cudbird, Toronto; Chairman, Board of Trustees, William Clark, Cleveland; Trustees, John R. Hass, Chicago; and J. L. Lambert, New York City.

LOUIS J. CUDBIRD,

Chief Engineer, City Hall, Toronto, elected "Grand Guard" of the Universal Craftsmen Council of Engineers at the twenty-first annual convention held in Rochester, N. Y., Aug. 6—10.

It was decided that the convention for 1924 would be held at Chicago.

At the third annual convention of the ladies' grand council of the Universal Craftsmen Council of Engineers, held in conjunction with the twenty-first annual convention at Powers Hotel, Rochester, N. Y., August 5-10, Mrs George Aldridge, 38 Rowntree Ave., Toronto, was elected "Grand Chaplain."

Eugene Tanguay, managing director of the Quebec Power Co., of Quebec, previously the Public Service Corporation of Quebec, has been appointed general manager of the Quebec Railway, Light, Heat & Power Co.

Preventing Scale by Treatment of Feed Water

*By **ARTHUR MURPHY**

A Description of the Impurities in Water Causing Scale—The Meaning of Hardness—Common Methods of Softening—The Value of Chemical Analysis

THE production of steam at low cost is, in the last analysis, dependent on the condition of the interior of the boiler, which in turn is influenced by the quality of the feed water.

In a modern plant employing the latest methods of burning fuel, high efficiencies are obtained in the furnace, but unless the boilers are kept clean and free from scale, the overall efficiency may be considerably reduced as a result of the heat insulating properties of scale.

In spite of frequent cleaning, either by turbining or other mechanical means, a boiler remains clean for only a relatively short time. Scale begins to form again as soon as operation is renewed and continues to increase in thickness until the boiler is cleaned again, the result being equivalent to a constant layer of scale having half the thickness of the layer at the time of removal.

For years engineers were content to allow the scale to form before by tedious labor, removing it. When it was seen that modern chemistry was of use outside of the laboratory a more logical method of dealing with scale forming water was developed, namely the removal from the water of scale forming substances or their transformation into compounds which are not scale forming.

Contaminated by Refuse

With some feed waters, more especially those in districts where the supply has been contaminated by refuse from factories using acids or acid forming compounds in their processes, excessive corrosion of the interior of the boiler often develops and since the results are not apparent except by careful examination, considerable damage may be done to the boiler.

The first step in purifying feed water which gives trouble in the boiler, is to find out the nature and the amount of each scale forming substance carried by the water. This necessitates a proper chemical analysis by one familiar with boiler feed water treatment.

Partial success sometimes results from the use of home recipes, but unless the impurities in the water and their amount are known, it is difficult to give the proper treatment for scale prevention. Under treatment will still leave a certain amount of scale while over treatment is wasteful and sometimes the cause of priming or foaming.

The ideal water for use in steam boilers would be distilled or pure rain water, then boilers would be free from scale and require but infrequent cleaning. Unfortunately such water is seldom available, the nearest approach being in large central stations or heating plants where the condensate is returned to the boiler.

There is every good reason why only pure water, or at least water free from scale-forming constituents, should be used in steam boilers. And fortunately it is not difficult to obtain such a supply of water no matter what the nature of the natural supply. Where the natural water is such that it cannot properly be softened, there is still the opportunity to use a distilling plant, or evaporator, to supply distilled water for boiler feed.

Many plants are faced with the problem of having to use practically 100 per cent. make up and where the water contains scale-forming compounds great difficulty is experienced in keeping the boilers clean.

The presence of scale forming compounds in the water is known as hardness and the rapidity with which the boiler scales up is a rough measurement of the degree of hardness. On boiling, some compounds precipitate from the water, others require chemical treatment for their removal. Hardness, which can be removed by boiling, is known as temporary, that which remains is called permanent, the sum of the two being called the total hardness.

The chemist measures the degree of hardness by the amount of standard soap solution required to produce a permanent lather.

All natural waters contain some impurities, about two degrees of hardness being the minimum. In addition to the dissolved compounds, sediment, mud and finely divided materials are frequently carried in feed water.

Hardness in water is caused chiefly by the presence of calcium and magnesium salts occurring in the form of bicarbonates, carbonates, sulphates and chlorides.

Calcium Present

The presence of calcium carbonate is the chief cause of temporary hardness, most of the other compounds causing permanent hardness which is not removed by boiling. Calcium carbonate or limestone ($CaCO_3$) though to a slight degree soluble in water, in the presence of carbon dioxide, is changed to calcium bicarbonate which is readily soluble in water.

The process of treating water to render it suitable for boiler feed purposes may be divided into two classes. the mechanical and the chemical.

The mechanical treatment, called filtering, is a means of straining any particles floating in the water is in use for removing sediment, mud and vegetable matter. The chemical means for the treatment of hard water for boiler feed may be divided into

(a) The introduction of compounds directly to the boiler by way of feed water.

(b) Introducing softening compounds into the water in large outside settling reservoirs.

(c) Passing the water under pressure through a mass of softening medium.

Use of Filter

Filtration, though closely connected with the chemical treatment of feed water is in reality a mechanical operation, consisting in the removal from the water of any finely divided materials floating or carried in suspension. A filter may be considered as a screen with very fine mesh.

Water that to the eye seems perfectly clear may carry a considerable amount of foreign material which the filter will remove, especially when in the form of a light colored, finely divided precipitate. Large settling tanks used in conjunction with the lime-soda treatment of water leave a certain amount of the precipitate in the feed water and being the finest precipitate, a filter is the most practical method of removing it. From the nature of the action of the filter, unless some means of cleaning at regular intervals is provided, the capacity steadily decreases until the filter becomes so clogged that it often can no longer be used.

The usual method employed is by back-washing or reversing the flow of the water for a short time. In this operation the velocity of the water should be much greater than when it is being used for filtration. By using high velocity for a short time much more effective cleaning is affected than by use of the same amount of water at a lower velocity. In back-washing filtered water only should be used, the use of raw water leaves a deposit which will be carried to the boiler as soon as normal operation is resumed and furthermore any deposit left during the back-washing period has a tendency to permanently clog the filter.

---

*Editor of Power House.

In many power plants, the first method, that of adding a boiler compound to the feed water and allowing the reaction to take place within the boiler is in general use with satisfactory results.

Heating water drives off any carbon dioxide and also changes the soluble calcium bicarbonate to calcium carbonate, which, being practically insoluble, precipitates, collecting on the tubes and the boiler shell as scale, unless the boiler is blown down at frequent intervals.

Lime and Soda Used

The chemical treatment of a water containing calcium bicorbonate is usually accomplished by means of milk of lime or water containing an excess of lime. The reaction depends on the fact that the excess carbon dioxide is removed by the lime, turning the soluble bicarbonate into the insoluble carbonate.

Soda ash or sodium carbonate is required by some waters to soften them, others require both the soda and the lime.

Magnesium bicarbonate is treated with lime to form magnesium hydrate. As magnesium carbonate is soluble it will not precipitate until boiler concentrations are reached.

Calcium sulphate is treated with sodium carbonate, resulting in the formation of calcium carbonate and sodium sulphate, the calcium carbonate being insoluble, precipitates, the sodium sulphate remaining in the water in solution as like all sodium compounds, it has no scale forming properties.

Magnesium sulphate requires both lime and soda for treatment. A double reaction occurs, the lime causing calcium sulphate to be formed, which in turn is acted on by the sodium carbonate, resulting in the formation of calcium carbonate which, being insoluble, is precipitated.

For the removal of calcium chloride, sodium carbonate alone will suffice, forming calcium carbonate. Magnesium chloride requires both lime and soda.

The amount of lime and soda used should always be slightly in excess of that theoretically required. too little will leave some hardness in the water. an excess unduly raises the concentration of the water in the boiler.

Two Types in Use

For the chemical softening of water by the lime soda process there are two methods, the hot process and the cold process. The chemical reactions in each process are identical but as the reactions take place much more rapidly at high temperatures, smaller tanks and settling chambers are required with the hot method.

The essential parts of the chemical softener are:

(1) A tank or tanks for the reactions and the precipitation of the insoluble compounds formed during the reactions.

(2) A suitable means of automatically adding to the water the correct proportions of the chemicals.

(3) A filter to remove any precipitate which has not settled out in the settling tanks to prevent it being carried to the boiler.

Various automatic devices are on the market for controlling the amount of the chemicals fed to the water, but as the hardness in water may vary from day to day, the companies often furnish small testing equipment by means of which the engineer can sample the feed water from time to time and determine the proper amount of chemical to be used.

The hot process is favored by some engineers, especially where the feed water is heated by exhaust steam before entering the boiler. In this way the feed water heater and the hot process for softening the water can be combined.

Reactions in the lime soda process are almost instantaneous in water over 200 deg. F., whereas with cold water several hours are necessary to insure completion.

The advantages claimed for the hot flow treatment are numerous, the driving off of practically the whole of the dissolved gases, preventing corrosion in the boiler, the saving due to exhaust steam heating the water which otherwise might be wasted; complete reaction within the tanks preventing scaling of the boiler feed pumps and pipe lines, the fact that the sludge formed is insoluble in hot water, so that when the water enters the boiler it has a very low residual hardness, and the small tanks required for the reactions.

On the other hand the cold process offers better control of the reaction and more time for the precipitate to settle.

Blow Down Losses

Blowing down is essential to keep a boiler clean, and when compounds are used, to keep the concentration down to a point that will insure freedom from priming and foaming. No more blowing down than is necessary should be resorted to, however, as it is wasteful.

Assume that in a modern boiler room supplying steam for industrial purposes at 200 lb. gauge and at 388 deg. F. the water rate is 12,000 lb. per hour., with boiler feed at 60 deg. F., If 5% is a normal amount for blow down then

Water blown down per H.P. hr.=60 lb.

Heat lost per H.P. hr. in blow down .60 x (361-28)=200 B.t.u.

Useful heat in one lb. of coal 9 x 1171 =10,539 B.t.u.

Coal consumed per hour in blow down

$$\frac{200}{10{,}539} = .019 \text{ lb.}$$

If the coal cost $7 a ton at the plant and $1 to get it from the yard to the furnace and to fire it, the cost of blowing down per year for the 1 000 H.P. boiler room is

$$\frac{1000 \times .019 \times 8760 \times 8}{2000} = \$665$$

Exchange

The latest method of softening water for boiler feed purposes consists of a tank containing a thick bed of artificial or natural mineral, more or less finely ground.

This mineral turns the hardening salts in the water into others which are not scale forming. The principle involved is the transference of the salts of calcium and magnesia into the non-hardening salts of sodium by contact with the filter bed. As the water is passed through the filter and discharged as softened water, the sodium salts in the bed are gradually changed to calcium and magnesium salts.

The rate of flow through the filter has little or no effect on the reaction provided, of course, that sufficient time is given for the exchange to take place. As it is solely a matter of exchanging sodium salts for calcium and magnesium, then after each regeneration only a definite amount of water can be softened. The frequency of regeneration is then dependent on two factors, the hardness of the water, and volume.

Announcements

The name of the Quebec Railway, Light, Heat & Power Co., has been changed to the Quebec Power Co.

E. Laurie Co., 243 Bleury St., Montreal, has been awarded the contract for furnishing a 6,000,000 gal. pump for the Notre Dame de Grace pumping station.

Fraser & Chalmers of Canada, Ltd., Canada Cement Building, Montreal, have received an order from the Corporation of the City of Swift Current, Swift Current, Sask., for a 700 gallon centrifugal pump direct connected to a 67 K.V.A. synchronous motor, together with necessary starting equipment and control panels.

Through Arthur S. Leitch Co., Kent Building, Toronto. the following installations have been made recently:—

Two duplex condensation pumps, one motor-driven and the other with coppus steam turbine, in the Ford assembly plant, Toronto. Long & Edwards, New York, contractors.

A Sim's heater in Trinity College school. Port Hope Ont., Bennett & Wright, 72 Queen St., E., Toronto, contractors.

A Sim's heater in the Hamilton Hospital, Hamilton. E. J. Madden, Hamilton. contractor.

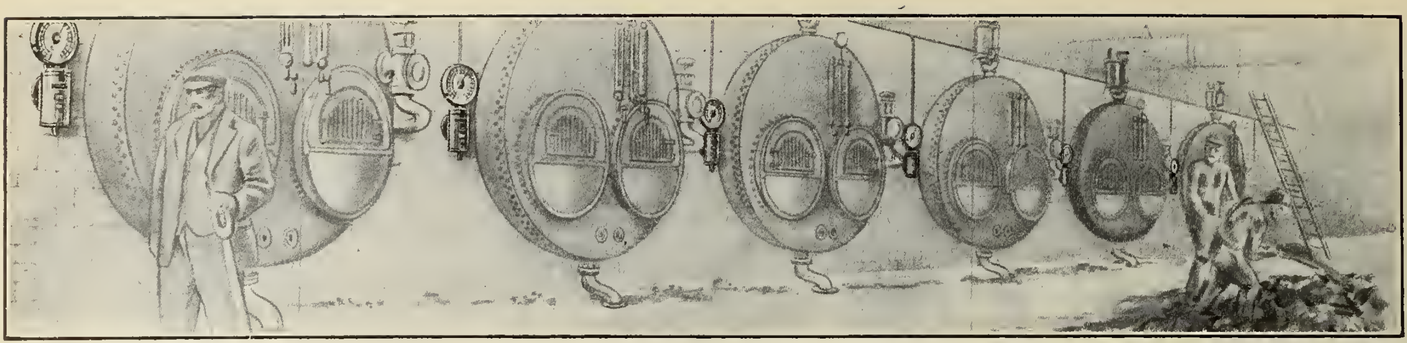
Sim's heaters. and Armstrong traps. for the Toronto Housing Commission. Bennett & Wright, 72 Queen St., E., Toronto, contractors.

Jenning's pump, for hytor vacuum heating system. in the Silverthorne School, Silverthorne, Ont.

Kieley reducing valves. and Armstrong traps in the plant of the Reg. N. Boxer Co., Foy Building, Toronto.

Jennings hytor-vacuum heating pump in the Courthouse at Portage la Prairie. Man.

Sim's heater and generators at the Weston Sanitorium. Weston. Ont.



Easy Engineering Lessons in the Power House

By **M. BARRY WATSON, B.A.Sc., M.E.**
Director of Engineering, Central Technical School, Toronto.

THE USE OF SUPERHEAT

THE extensive use of superheated steam in power generation is a comparatively modern practice, although for many years previous to its general adoption engineers had appreciated its value in increasing steam engine economy. The chief reasons for the delay in its practical adoption were due solely to mechanical difficulties in its production and use, and the increased cost of maintenance consequent on its use.

In recent years the above mentioned difficulties have been largely overcome, so that to-day superheated steam is used extensively in all large plants, and is quite usual in locomotive practice.

What Superheat Means

Before going further it may be well to give a short explanation of what superheat means as applied to the generation and use of steam. Water, when heated in a closed vessel, commences to turn into steam, which as long as there is still some water remaining, is known as saturated steam. If more heat is added to the vessel, more of the water will be turned into steam without any increase in temperature if the pressure is kept constant.

There is always a definite relation between the temperature and pressure of saturated steam. That is, saturated steam at any particular pressure always has the same temperature. However, if some of the saturated steam is allowed to flow into another vessel where no water is present, and heat is added to it, the temperature of the steam will rise even though the pressure is held constant. This steam of a higher temperature than that corresponding to its pressure, is known as superheated steam.

Temperatures in engineering work are measured in degrees Fahrenheit, while amounts of heat are measured in British thermal units. Superheat is measured in degrees F. and while engineers very often speak of the "amount of superheat," it would more correctly be spoken of as the "degree of superheat." However, the "amount" or the "degree" of superheat is expressed as the number of degrees F. by which the temperature of the steam in question exceeds the temperature of saturated steam at that pressure.

For example, let us suppose our steam gauge reads 140 lbs. per sq. in. pressure while our steam thermometer reads 480 degrees F. By reference to a steam table, we find that the temperature of saturated steam at 140 pounds gauge pressure is about 361 degrees F. Thus the steam in question would be said to have 480—361=119 degrees of superheat.

How Superheat is Obtained

The superheating of steam is accomplished by passing the steam after it is drawn from the boiler through a series of tubes which are in contact with the hot gases from the fire. These tubes may be incorporated as part of the boiler unit as shown in Figure I, where the hot gases come in contact with them after having come through the first pass of the boiler; or they may constitute an independent unit known as an independently fired superheater.

In the separately fired superheater there is sometimes a separate section functioning as a boiler operated in conjunction with it and which adds its steam to that of the other boilers supplying the superheater. The purpose of this boiler section is to take the first intense heat from the gases after they leave the fire, because steam alone in the tubes will not absorb heat fast enough from the tubes to keep the latter from burning if the temperature of the gases circulating around them is much over 1,500 degrees F. whereas water has good heat conductivity and will keep the tubes sufficiently cool to prevent burning with even the hottest fire temperatures on the other side of the tubes.

Burning Out Tubes

In connection with the final statement above, it is sometimes asked why it is that boiler tubes have been known to burn when there was water in the boiler. The answer is that there could not have been water in contact with the tube that burned, and there are two causes for such a possible condition to exist.

First, and most usual cause, is a thick coating of scale on the tubes which keeps the water out of contact with the tubes, and itself being a fairly poor

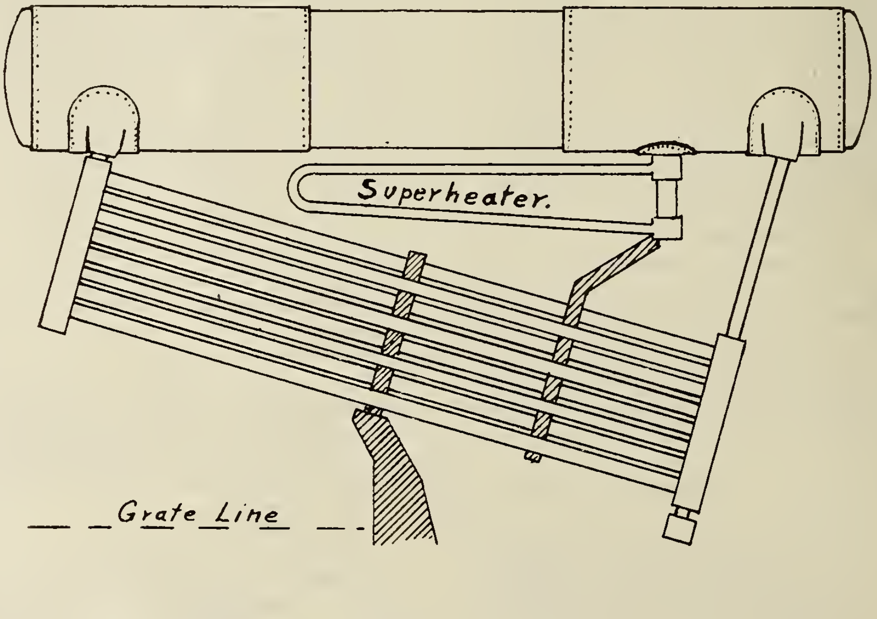


FIGURE I.

conductor of heat does not keep the tube below the burning temperature of the steel.

Secondly, the circulation of water in the tubes of some boilers may become so poor, usually on account of dirt in the boiler, that the steam may not be able to rise into the body of the boiler as fast as it is made, and may therefore fill a tube with nothing but steam, when of course there will not be water in contact with the tubes.

Another type of superheater consists of a number of close bent tubes, one of which is illustrated in figure II. The two ends of each bend connect to headers in the smoke box while each bend extends into one of the fire tubes of a fire tube boiler. This type is extensively used in locomotive practice. Its chief objections are the extra resistance to the draft, and the fact that the superheaters must be removed when the tubes are to be cleaned.

Why Superheat is Used

The primary object of using superheat in steam power work is of course economy of fuel. We shall now try to understand at least some of the reasons for this increase in efficiency with the use of superheat. In the first place the thermodynamic efficiency of the steam engine depends on the difference in the temperatures between the entering and the exhausting steam. The writer will not try to explain this fact in this short lesson, but will try to show that by the use of superheat we will get a greater difference in temperature between the live and exhaust steam, therefore from the above stated fact it will be seen that the efficiency of the engine will be increased.

Let us look for a moment at the action of steam inside an engine cylinder. If the steam is saturated, when it first enters the cylinder it starts to warm up the walls of the cylinder, thus some of the steam condenses and makes room for more to be forced in from the valve chest. In the case of superheated steam, a small loss of heat will lower the temperature without causing condensation, therefore there will be less of the superheated steam used per stroke with the same pressure and valve setting. At the same time it is found that superheated steam will not conduct heat nearly as well as saturated steam, therefore the cylinder walls will not be able to absorb so much heat, even though the temperature of the steam is higher. When the steam has expanded and its temperature has gone down, the water that was condensed in the case of the saturated steam is now cooler than the cylinder walls and re-absorbs some of the heat which it gave up and turns back into steam, too late, however, to produce any power worth considering, but raising the exhaust temperature and pressure. In the case of the superheated steam there is really less steam in the cylinder, there is no water to absorb heat and evaporate, and the conductivity of the superheated steam is so poor that it does not asborb enough heat from the warm cylinder walls to seriously increase the temperature or pressure of the exhaust steam. Thus the engine is seen to use less steam per stroke, and to have a lower exhaust temperature when using superheated steam, increasing the efficiency in two ways.

Besides the above advantages of superheat there is the advantage of having no drips or condensate from the steam mains or headers to take care of as the loss of heat from the piping merely reduces the superheat instead of condensing part of the steam. Also the steam arriving at the engines is always perfectly dry which precludes the necessity for separators and traps and prevents knocking in the engine, or pitting of turbine blades.

There is also a considerable saving in boiler capacity, or a bigger load may be carried on given boilers when superheat is used, because so much less superheated steam is used than when saturated. The same applies to the condenser and vacuum pump equipment. These represent a considerable saving in a large plant, not to mention the saving in cooling water and boiler feed equipment which may be effected.

Objections to Superheat

The chief difficulties met with in the use of superheat were in the maintenance of packing and lubrication. However, packing and oil manufacturers have now on the market goods which give perfect satisfaction and reasonable life with superheats higher than those most common in steam plants. Some engineers used to be of the opinion that the working of steam at such high temperatures and the freedom from water in the steam might weaken the piping, etc., sufficiently to cause extra hazard. However, as the majority of plants do not carry more than from 100 to 200 degrees of superheat, this is not a serious matter. Where high pressures and high superheat are used, however, the very best steel piping and fittings etc. must be used to have the requisite mechanical strength.

When connected in a circuit never leave the secondary of a current transformer (instrument transformer) open-circuited. Excessive voltage will be induced in the secondary and may break down the insulation or cause the transformer to heat excessively. If it becomes necessary to remove the instrument which the transformer serves, short-circuit the secondary with a jumper before disconnecting the instrument leads.

* * *

Engineer (trying to cut steak at Rochester convention of U C.C of E.)—"Say waiter, how was this steak cooked?"
Waiter—"Smothered in onions, sir."
Engineer—"Well, it died hard."

* * *

All solid foreign matter can be removed from transformer oil by putting it through about three thicknesses of bolting cloth. The best method for removing moisture is to pass the oil through a filter press. Transformer oil is considered in good condition when it does not break down at less than 40,000 volts impressed on ⅜-in. spheres, set 150 mills apart.

* * *

A Hamilton engineer was out still hunting last Saturday but after mooning around all afternoon all he succeeded in getting was a couple of swallows.

* * *

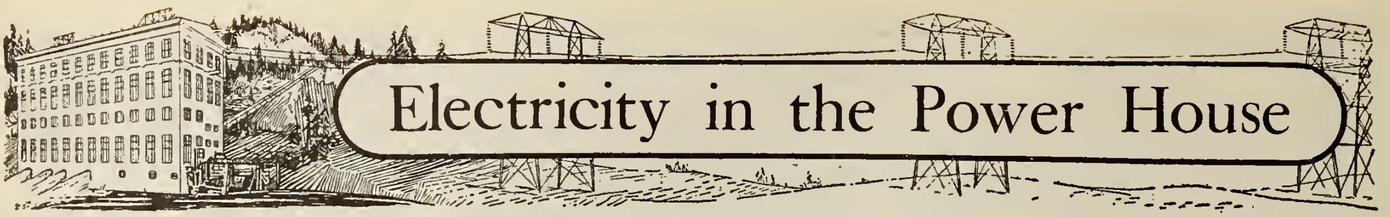
Although an oil-cooled, oil-insulated transformer is one of the most simple pieces of electrical equipment, it nevertheless should not be expected to operate continuously after being put into service without attention. An inspection should be made about once every six months. This should include a test of a sample of the oil drawn from the bottom of the tank and an examination of the interior of the tank.

* * *

Although many engineers insist that Adam was born in the morning, it is now generally believed that he was born a little before Eve.

* * *

When a battery is to remain out of commission for several months, give it an overcharge before allowing it to stand idle, and then, if possible, a freshening charge for about two hours every two months. If this cannot be done, the battery may be allowed to stand for not over six months without charging. Then the battery should be charged for about 50 hr. at half normal rate.



Electricity in the Power House

By J. A. BURNETT, M.E.I.C., Consulting Engineer, 513 New Birks Bldg., Montreal.

THE induction motor as installed and in daily service, is a remarkable development of recent times. Simple, reliable and reasonable in cost, it runs day in and day out. As made by standard companies, with good iron, insulated coils, and decent bearings, it requires little attention.

The design of the motor may be compared to a transformer, but with a moving (rotating) secondary. By the "primary" of an induction motor is meant, that part which receives energy by direct connection to the source of electric energy; the other member being called the "secondary." That member which remains stationary is called the "stator," and the revolving member is called the "rotor."

A "squirrel cage" rotor is one in which the conductors are straight bars of copper, connected together at each end of the rotor by copper rings. The windings comprising the primary are so grouped that, in case of a three-phase motor, there ensues a rotating field of energy, caused by the polyphase nature of the entering current, and as these phases rise and fall in value, the combined effect of the three groups of windings is merely to cause a rotation of these polar regions in the iron frame.

Number of Poles

The "number of poles" is always equal to the number of bands of conductors into which the total winding of each phase is divided. The bands of conductors forming one phase usually overlap the bands of conductors forming the other phase, there being then two or more conductors per slot. Now, when a three-phase voltage is impressed in the primary winding, the resultant magnetic flux in the iron remains constant in value at all times, but travels around the air gap with a speed of $N = \frac{120 F}{P}$ r. p. m. where f is the frequency of supply and p the number of poles.

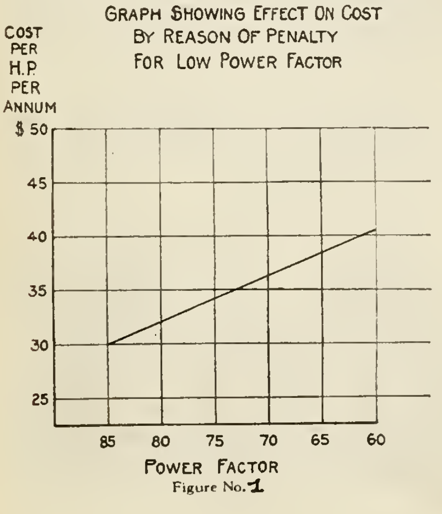


Figure No. 1

The speed of rotation of the air-gap flux, namely, the speed N given by the above formula is called "synchronous" speed. At light loads the speed of the motor is very nearly equal to this speed. The slip of an induction motor is the ratio of the difference between the actual speed (N_1) of the rotor and the synchronous speed (N) to the synchronous speed (N) or $S = \frac{N - N_1}{N}$. The slip is usually expressed as a percentage. The slip at standstill is unity; at no load it is very nearly zero.

Proportional to Slip

The electromotive forces in the secondary of the polyphase induction motor are induced by the rotation of the flux produced by the currents in the primary windings. The rotor electromotive force is therefore proportional to the slip and has a frequency equal to the product of the slip by the frequency in the primary. A noticeable feature is that the force on each conductor is always in the same direction and the total force acting on all the conductors is practically constant for a given value of the slip.

The current set up in the secondary of an induction motor produce a rotating flux, which travels with the same speed with respect to the primary, and in the same direction as the flux set up by the current in the primary, but the direction of this secondary flux at any point in the air gap is opposite to the direction of the primary flux. When there is current in the secondary the resultant flux is equal to the difference of these two fluxes. The primary current which would be necessary to produce this resultant flux is called the "magnetizing" current.

The rating of an induction motor should be the load in horsepower which it will deliver continuously at the shaft with a maximum rise in temperature of any part not exceeding 50 degrees centigrade by thermometer. However, certain motors for intermittent work, such as hoists, elevators, cranes, and swing-bridges, are rated in accordance with the output they will give for one hour. Any motor should be able to carry momentary overloads without "breaking down," as it is called, which means gradually decreasing in speed to a standstill when the load is excessive. The maximum output of the motor should be 50 per cent. greater than the rated output.

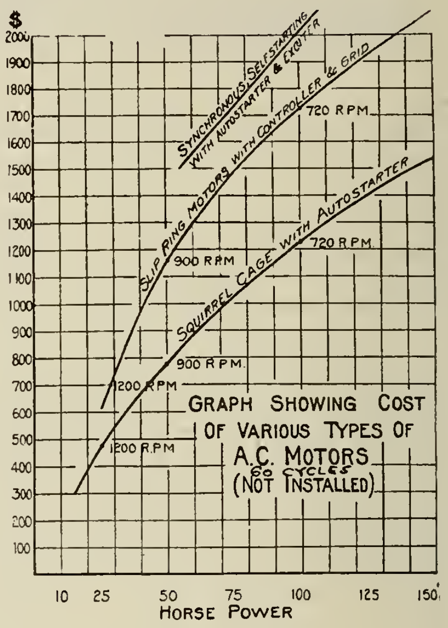

Figure No. 2

Prevailing Voltage

The prevailing voltage in Eastern Canada is 1 h.p. to 100 h.p., 550 v., and for 100 h.p., and up, 2200 v.

The prevailing frequency in Eastern Canada is 60-cycles per second. The Hydro-Electric system of Ontario is mainly 25 cycles. The 25-cycle motors cost about 10 per cent. more than 60-cycle motors owing to the larger amount of iron and copper required.

The designers of induction motors endevor to produce motors with as small an air gap, between rotor and stator, as may be consistent with mechanical operation. The air gap is generally one mil for each inch of rotor diameter, to be more exact:

Rotor Diameter	Air Gap
12 to 26	.032 in.
26 to 50	.050 in.

It can be seen, therefore, that in order to obtain a good power factor, (kilowatts ÷ kilo-volt-amperes) a motor with a fairly small diameter rotor is desirable. Thus the favorite speeds may be taken as follows:

Motor Rating	
0—10 h.p.	1800 r.p.m.
10—30 h.p.	1200 r.p.m.
30—50 h.p.	900 r.p.m.

Low Power Factor

Owing to the fact that the standard form of electric power contract exacts a penalty from the consumer for low power factor, this feature is now receiving the attention of power users. This

(Turn to page 43)

Practical Ideas From Practical Men

*OIL OR COAL

MANY Canadian engineers, confronted with the problem of discarding coal as a fuel in favor of oil, are interested in determining whether or not such a "change over" will prove economical in their plant, and the accompanying chart may prove of value in deciding the question.

To use the chart it is merely necessary to zigzag across as indicated by the dotted lines and column G, which is pointed at by the arrow at the top, tells the number of B. t. u.'s there are to each ton of coal or gallon of oil purchased. That is, column G applies to both oil and coal.

In figuring the oil begin at the left and zigzag toward the right to column G. In figuring coal begin at the right and zigzag toward the left to column G. If the oil, for instance, contains 20,000 B. t. u.'s, and the specific gravity is 0.9, and if the boiler efficiency with oil fuel is 80 per cent., the zigzag dotted line respective figures show that each cent will buy 24,000 B. t. u.'s.

Begin at the 5c. column A, and run through the 80 per cent., column B, with a straight line. This locates the intersection with column C. From this intersection in column E go through the 0.9 column F, and the final intersection with column G gives us the answer—24 000 B. t. u.'s for each cent.

Now comparing with coal, we begin at the right. If coal costs $8,00 per ton of 2,000 lbs., and if the boiler efficiency, using the same boiler as above is 70 per cent. with coal, and if each lb. of coal contains 11,000 B. t. u.'s, each cent will buy about 19,200 B. t. u.'s, as shown in column G.

As will be noted, the $8.00 is found in column L, 70 per cent. boiler efficiency is in column K. Run a straight line through both points and locate the intersection in column J; run a straight line through the 11,000 in column H, and the intersection with column G gives us 19,200 B. t. u.'s.

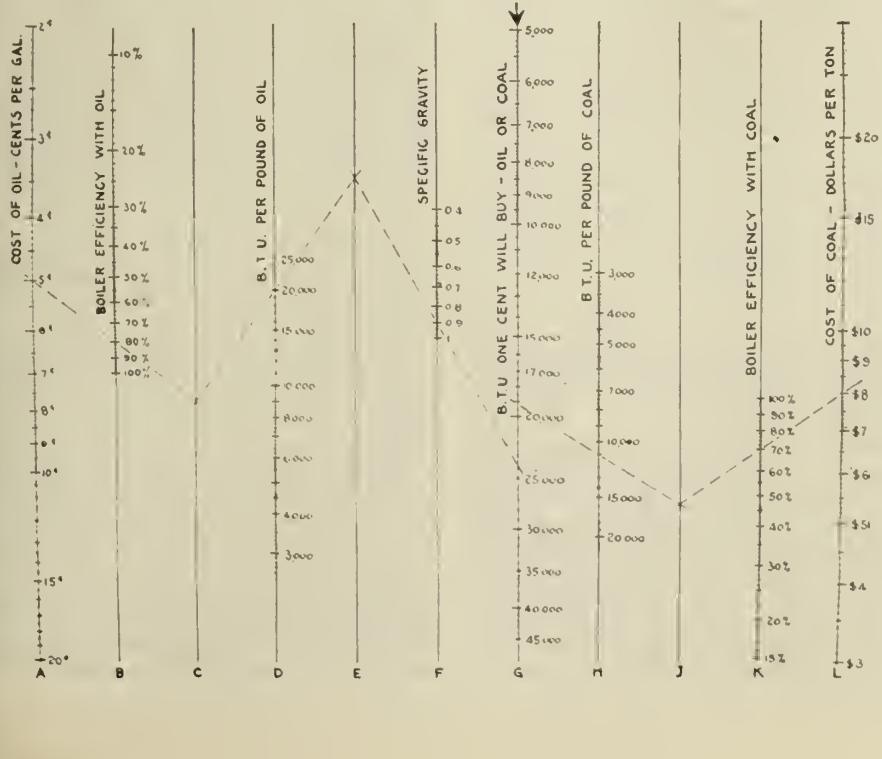
In other words, the solution of this problem indicates that the use of this oil at 5c. per gallon will furnish nearly 5,000 B. t. u.'s more for each cent than will coal at $8.00 per ton.

In using column A the cost per gallon should include all costs—cost of hauling, cost of storing, etc.

It is well known that boiler efficiencies with oil are usually greater than with coal. The difference, it has been claimed, is as much as 10 per cent., as in this problem where we use 80 per cent. column B and 70 per cent. in column K.

Specific Gravity

Regarding specific gravity, given in column F, an easy way in which to determine this is to take any vessel, such as a pail, jug, or bottle, and weigh it. Then fill it with water and weigh again. Subtracting the weight of the vessel gives us the weight of the water. Now do the same with oil and the exact weight of the oil by the weight of the water. The quotient is the specific gravity. The less delicate scales used for weighing the greater should be the size of the vessel.



Where a sample of the oil is not available and where the density of the oil is given in degrees, Baume, the following table will be found useful in connection with column F:

Degrees Baume	Specific Gravity
10	1.0
15	0.97
20	.93
25	.90
30	.88
35	.85
40	.82
45	.80
50	.78
55	.76
60	.74
65	.72
70	.70
75	.68
80	.67
85	.65
90	.64
95	.62
100	.61

To calculate the specific gravity, knowing the degrees Baume, simply add the degrees Baume to 130 and divide the sum into 140. The quotient is the specific gravity.

As for the cost of coal, column L, this is similar to column A and must include all costs, such as hauling, storing, pulverizing, and, if purchased some time ago, the interest on the purchase price.

Solves Other Problems

This chart may be used in several ways for solving various problems. Thus, by zigzagging clear across from left to right from column A to column L; knowing the cost of oil and all the necessary intermediate factors, column L gives the equivalent cost of coal. Or zigzagging toward the left from column L we get the equivalent cost of oil.

Thus, with coal at $6.00 per ton, and the boiler efficiency at 70 per cent., we would find that a heat value of 10,300 B. t. u.'s per pound of coal would give us no advantage in using oil as regards cost of oil. But oil has other advantages, such as less labor required for firing, less storage space required, etc.

All of these points must be given consideration before one can decide whether oil should be used in preference to coal.

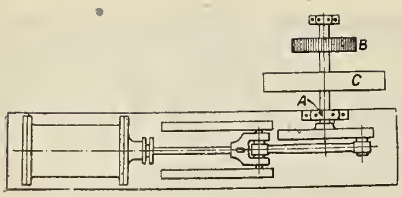
TRUEING A SHAFT

The following sketch shows a simple horizontal steam engine, 10-in cylinder diam. by 18-in. stroke, which once became uncoupled while running, owing to the crosshead cotter working out. As would be expected, considerable damage was done, and among other things the crankshaft was bent at the journal A, giving a "wobble" of about 2½ in. at the perimeter of the disc crank.

On the crankshaft was a steel gear wheel B, in halves, which transmitted

---

*Copyright 1923 by W. F. Schaphorst.



Trueing a Shaft.

the drive, also a heavy solid flywheel C, which had practically "grown on" the shaft, and which defied all attempts at trying to move it. As the job was making slow progress, the following method was tried:

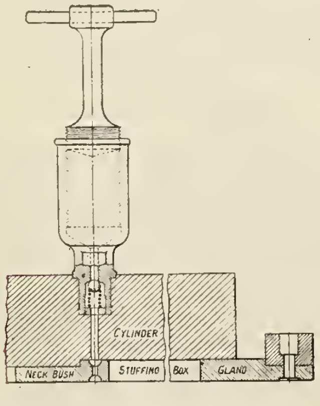
First, the steel wheel B was removed, then the brasses in the bent journal pedestal were "let down" until there was a slight amount of "nip," the big and little end cotters were eased back. The engine now having no load, was run sharply for five minutes, during which time the cap bolts at A were tightened, and thus nipping the shaft, until it was thought to be sufficiently hot. The engine was then stopped and a screw jack placed against the full part of the crank case, and it was pushed back until it ran practically dead true.

The journal was afterwards filed up, and the brasses refitted, and the engine ran for some years after the above incident, without any further trouble.

LUBRICATING RAMS

Provisional protection has recently been granted in Great Britain for a system of lubrication which will be of interest to engineers generally.

It is a well-known fact that so long as the packing contained in any stuffing-box can be kept lubricated, so long will the packing last and thus prevent the scoring of the ram. The idea consists in the placing of a lubricator on the inside or pressure side of the stuffing-box. The flange of the neck bush is grooved round the outside and inside and a number of holes drilled to connect both. The lubricator, which is provided with a non-return valve, is fixed so that the grease finds its way round the outer groove through the drilled holes into the inner groove and from there on to the ram or rod and through the packing.



Lubricating Rams.

The ram and packing are thus lubricated during the no-pressure stroke, while during the pressure stroke the pressure itself forces the lubricant through the stuffing-box.

This system was installed three months ago on a set of high-pressure hydraulic pumps which had been giving the usual trouble met with on this class of machinery, viz., scoring of rams and continual re-packing.

When the pump had been running two months all the packing was taken out for inspection and found to be as good as new and well saturated with grease. Naturally, working under such conditions, no scoring of the rams had taken place. Ordinary hemp packing was used, which, besides being much less expensive, absorbs the grease better than the more expensive fabric packings.

Efficiency Now C.A.S.E. Goal

Executive Secretary Lauds Educational Value of Melvern F. Thomas Article in Power House

By GEORGE J. SOUCY

QUITE recently an excellent and timely article appeared in Power House, written by Melvern F. Thomas, on the subject of Power Plant Efficiency, which tended to show that this much-desired result was dependent on the engineer. I would urge all engineers who have not read this article to obtain a copy of the June 20 issue of Power House and consider all the points set forth in it. Every engineer would then come to the conclusion that he should avail himself of any opportunity offered to acquire the knowledge and competency which will enable him to operate a power plant efficiently.

The Canadian Association of Stationary Engineers of the Dominion of Canada encourage the technical education of stationary engineers and propose to supplement same wherever the opportunity offers by forming classes under the guidance of practical engineers to demonstrate the practical application of technical education. The C.A.S.E. was a pioneer in the matter of technical education in Canada and it is to be noted that the first industrial board formed in Toronto for the technical education of the workers was championed by the founders of the C.A.S.E.

While the C.A.S.E. has not made the progress it should have, it still has opportunity to serve ambitious engineers, and if it renders that service there need be no doubt as to its future popularity.

Raps Lack of Interest

In regard to the lack of interest in the question of power plant efficiency, there is no need of avoiding the issue. Many engineers make no effort to equip themselves with the necessary knowledge and training to operate a power plant efficiently because they feel that "no substantial encouragement has been offered them," and that they "are merely a necessary evil to plant operation." Further, they conclude wrongly that no amount of saving in fuel or maintenance cost will elevate their position or gain recognition from their employers.

That, of course, is an entirely wrong conclusion, for as soon as an employer is brought to realize, by articles such as that written by Melvern F. Thomas, that the engineer should be encouraged to operate his plant more efficiently, he will see that every opportunity is afforded his engineer to acquire the necessary knowledge and training to enable him to operate it efficiently. In fact, it will soon be recognized as a national duty by both the employer and the engineer to conserve our fuel resources, and that means the efficient operation of power plants.

To Extend Branches

As soon as there is manifested the demand in any locality for instruction and training, the C.A.S.E. will rise to the occasion and extend its branches. It now invites all those who are fitted by experience to instruct others to join the ranks and offer their service for the general uplift of their fellows, and to be ready to meet the demand which is sure to come soon for classes of instruction in practical operation.

Any information required will be furnished gladly by George J. Soucy, executive secretary of the C.A.S.E., 48 Moore Ave., Toronto.

Trade Catalogs

The Combustion Engineering Corporation, Limited, of Canada, have issued a new bulletin describing the Coxe Traveling Grate Stoker, emphasizing its performance in burning small sized anthracite coals and coke breeze. The special features claimed for this stoker are the control of the air to the fuel bed by means of compartments, rugged construction and ease of drive, special construction of the grate eliminating ash at the forward end of the stoker.

The Underfeed Stoker Company of Canada have issued a bulletin describing the new Riley Underfeed Super Stoker.

The advantages claimed for it are, long travel of the fuel, control of the air by dividing the underfeed section into two air zones with a separate zone for the overfeed section, a two speed gear box, the use of flared retort sides and moving high side tuyeres to control the fuel bed, a renewable wearing strip in each retort cylinder and the addition of a rotary clinker crusher.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

DAIRY REFRIGERATION

I desire information in regard to the different types of refrigeration and ice-making machinery now on the market. The particular installation in question is in connection with a small dairy plant. It will be necessary to make ice in moderately small quantities.—B. K.

Answer:—Usually small horizontal double-acting ammonia compressors, or small vertical single-acting enclosed type compressors are used for producing refrigeration for dairies. These compressors may be actuated by any type of prime mover. However, the best type seems to be the electric motor, and, then, after that, the steam engine.

Mechanical refrigeration in dairy plants is generally produced by the direct expansion of ammonia in coils which are submerged in brine. The brine is then in turn pumped to the rooms or apparatus where refrigeration is required. In a smaller sized plant, the storage brine and the size of the refrigeration plant is such that the machine need only operate eight to twelve hours per day and still maintain the required temperature. In slightly larger plants, the storage capacity of the brine is smaller and the ammonia compressor is relatively smaller, and the plant is made to operate throughout the twenty-four hours.

The design and specification of a refrigeration plant for a small dairy is a technical problem which can be solved after all of the factors are known. The most efficient manner of proceeding with this work is to ask for competitive bids from prominent manufacturers of refrigeration apparatus. You will find many advertisements of the manufacturers of apparatus in the columns of Power House.

PRESSURE LUBRICATION

A footstep bearing, on a vertical shaft 8 in. in diameter and about 50 ft. long, has been giving trouble. Suggestions would be welcomed for the lubrication of this by pressure, if it be possible, or would ball or roller bearings be feasible?

Ans.:—Under ordinary conditions it is, as a rule, not advisable to load plain footstep bearings to a greater pressure than 200 lbs. per sq. in. If special attention is paid to lubrication, this may be increased to 400 lb. per sq. in.

One of the methods of reducing the tendency to seize is to place a number of steel discs between the bearing surface of the shaft and the bearing itself. These have oil channels in the usual way, and are kept lubricated in the usual manner. The idea is that, if the lubrication between any pair of discs becomes faulty, there are still other surfaces adequately lubricated.

Although forced lubrication could, no doubt, be arranged, the cost of this would be very little different from the cost of having a roller bearing fitted, and the latter would soon pay for itself in the decreased attention required.

If the work is very heavy, the cylindrical type with divided rollers would, probably, be the best to install, but, under lighter conditions, the conical type would suffice.

TESTING AMMONIA

Will you advise us a simple method of testing anhydrous ammonia for purity.—J. T.

Answer:—The purity of anhydrous ammonia may be tested in a number of practical ways. The most common as well as the most effective test is that one of evaporation. To test a sample of liquid ammonia it is best to use a flat bottomed boiling flask with a wide neck, which can be obtained from any dealer in chemical supplies.

Some manufacturers supply these flasks and also a piece of bent pipe for withdrawing the sample. Care should be taken when the sample is being drawn that moisture is not allowed to get into the sample. Thus, care should be taken that frost from the connection or moisture from the atmosphere does not get into the sample. It is best to draw the sample on a clear day. It is advisable to evaporate the sample by immersing the flask in a pail of water. This allows an even boiling and allows one to see into the flask. If, as the evaporation continues, the liquid assumes a cloudy appearance and this becomes more pronounced before the end of the test, it is usually an indication that traces of lubricating oil are present.

After the liquid has been evaporated, any residue remaining in the flask constitute the impurities in the ammonia.

If water is present, it can be detected by the small globules or drops that adhere to the inside of the flask.

If the flask becomes perfectly dry after the evaporation, this indicates that there are no liquid or solid impurities in the ammonia. The evaporative test, however, does not disclose the presence of gaseous impurities.

The presence of foreign gases may be detected in the following manner:

A shipping cylinder containing liquid ammonia is stood on end with the valve uppermost. A short piece of ¼-inch pipe is connected to the valve on the drum and the opposite end is placed in a pail of water. When the cylinder valve is opened slightly, bubbles will appear on the surfaces of water if permanent gases are present. If these bubbles appear intermittently with a cracking sound, this indicates that a mixture of ammonia and permanent gases are leaving the drum. These, then, are the simple and practical methods of determining the presence of impurities in ammonia.

PRESSURE FALLING OFF

Indicator diagrams taken from a 10 x 16-in. D slide-valve engine with throttling governor show considerable falling off of the pressure during admission. Could not the engine develop more power if fitted with a shaft governor?—G. BROWN.

Answer:—The falling away of admission pressure when the engine is loaded, to obtain the lowest running position of the present throttling governor, may be due to contracted steam ports and passages, and there would be the same defect of diagrams made with a shaft governor and balanced valve. The cut-off could not occur so late in the stroke, and although there might be better speed regulation and higher pressure during admission, less power could be developed than from the later cut-off with the throttling governor.

ICE AND SALT

The writer would like to know why the temperature drops when ice and salt are mixed.

Also how low a temperature can be reached with a combination of salt and ice?

Could sugar be used as well as salt? The writer has been told that sugar will cause a lowering in temperature.—G. D. A.

Answer:—The reason for lowering of temperature in a mixture of ice and salt or any other substance lies in the latent heat of fusion or the heat required to be taken up in order to cause a solid body to assume a liquid form. Heat is required to make a liquid body pass to a gaseous form and is also required to pass a solid body to a liquid form just as heat is taken up when water is boiled into steam, and also heat is taken up when ice is changed from a solid state to a liquid (water).

Most substances when mixed or dissolved one in the other give out a little heat called the "heat of association," but in many mixtures the heat of fusion is greater and the net amount of heat that has to be added is greater (refrigeration). This heat required to fuse ice plus the heat required to melt salt or reduce both to a liquid state (brine) is greater than the chemical affinity of water and chloride of sodium—hence heat has to be taken from the substances that compose the mixture and so its temperature is lowered.

But the quantity of heat taken up available for refrigeration is small (although on a low plane of temperature) and the use of a mixture to produce low temperatures is only of service where small quantities of heat are required to be taken up at a low plane of temperature and it may be inconvenient or expensive to procure an apparatus to take up the heat (or produce refrigeration) at a much lower operating cost per unit of refrigeration produced. Where considerable quantities of heat are to be taken up it is cheaper to use another method.

The use of ice and a salt produces lower temperatures in the mix than a mix of a solid and water, though the latter can be used for the procurement of fairly low temperatures as a mix of nitrate of ammonia and water. In the first case it is evident that the ice already has a low temperature and contributes its heat of fusion as is also the heat of fusion of salt contributed, and the lowering of the temperature of the ice water and the lowering of the temperature of the salt (a small matter) to the final temperatures of the solution is not so great as it might be in the second case where the original temperature of both the salt and the water might be higher than ice. It must be remembered that the temperature obtained can never be lower than the freezing point of the solution. A mix of ice and water for example, cannot be finally lower than 32 as a mixture of 1 lb. of ice and 1 lb. of water at 176 F. will result in a mixture containing 2 lb. of water at 32 degrees.

A mix of 3 lb. of salt and one pound of ice can be made and a temperature of —5 F. obtained, which is about the lowest temperature that can be obtained by a mix of ice and salt considering the heat of fusion, the specific heat and the heat of association of ice and chloride of sodium. One pound of each will make a mixture that will go to about zero.

Sugar can be used mixed with ice to produce low temperatures, but the results will be slightly different on account of the slight differences of heat of fusion and the specific heat of sugar compared to salt.

Refrigerating effect is only obtained by the rise in temperature of the mixture. Chloride of calcium added to water produces heat in the mix—added to snow or ice it produces as low a temperature as —436, if mixed in the proportion of 2 lb. calcium chloride to 1 of ice, because of the original low temperature of the ice and the combined heat of fusion of ice and chloride of calcium which considerably overcomes the heat evolved by what might be called the chemical "heat of association."

The expense of boiling off the water of the solution in order to recover the salt so it can be used over again is vastly more than the expense of reducing an amount of gas to a liquid which by evaporating again to a gas will take up the same amount of heat (i.e., produce usable refrigeration).

SETTING PUMP VALVES

What is the method of setting the steam valves of a duplex pump?—WINNIPEG.

Answer:—The general rule for setting the valves is to place the pistons of both sides at the centre of the stroke and set the steam valves centrally over their ports. As there is lap, the outer edge of the valves will be on line with the inner edges of the steam ports. In that position the valve-rod clearance or lost motion of each valve must be evenly divided so there will be the same amount of lost motion for movement of the valve in either direction.

To place the pistons at the centre of the stroke, move them to contact first with one head and then with the other and mark the positions of each on its piston rod against the piston-rod gland. Then place a mark on each rod midway between the marks made at contacts and move the rods until the central marks come against the ends of the glands. The pistons then will be in central positions and the valve-motion arms should stand perpendicular to the piston rods. If that is not the case, the crosshead spools must be disconnected and the positions corrected. Next remove the steam-chest covers and place the slide valves centrally over the ports and adjust the lost motion so each valve will have the same clearance for movement in either direction.

PRESSURE GAUGES

In checking up a pressure gauge on a steam line, it is found that the gauge shows 10 lbs. higher than the actual pressure. Under the conditions is it proper to say that the gauge is heavy or that it is light?—O. N.

Answer:—A pressure gauge is said to be "heavy" when the pressure which it indicates is higher than the true pressure, and is said to be "light" when the pressure indicated is lower than the true pressure. The indications of a pressure gauge rarely are the same amount higher or lower than true pressure throughout the whole range of pressures indicated and a statement that the gauge is 10 lbs. heavy or light would be inexplicit unless coupled with a statement of true pressures at which the error occurs. When compared with a calibrated test gauge, the indications may be correct for the true pressure of 5 lb., but 10 lb. "heavy" or "light" for a true pressure of 50 lb. per square inch.

Personals

A. G. MacLachlan has been appointed assistant engineer with the Bancroft Power Co., Bancroft, Ont., with the hydro-electric power development.

H. P. Stephens, 2004 Dundas St., W., Toronto, has announced that he is in the power plant field as a consulting specialist in feedwater treatment for steam boilers.

Ewart G. Horne, formerly vice-president and manager of Lockwood, Greene & Co., of Canada, Ltd., has opened an office at 10 Cathcart St., Montreal, as consulting engineer.

C. J. Oliver, a 1923 graduate of McGill University, Montreal, has taken a position on the engineering staff of the Central Region of the Canadian National Railways, Toronto, in the mechanical and electrical engineering department.

A. S. Mansbridge has been transferred from the head office of the Trussed Concrete Steel Co., of Canada, Limited, Walkerville, Ont., to the Vancouver office of the company.

P. C. Ahern, a graduate in electrical engineering from McGill University, has been appointed to the engineering staff of the Canadian Westinghouse Co., Hamilton, Ont.

Brian R. Perry, formerly with Peter Lyall & Son Construction Co., has taken the position of representative of the MacKinnon Steel Co., Ltd., in Montreal.

It is reported that the directorate of the new Ottawa & Hull Power Co. will be composed of the following:—Sir Henry K. Egan, J. B. Fraser, John A. Cameron, and E. R. Bremner, all of Ottawa, and J. B. Woodyall, vice-president of the Southern Canada Power, and A. J. Nesbitt, of Montreal.

G. I. Hambly, manager of the sales department of the Imperial Oil, Limited, Toronto, has retired, and Col. E. A. Olver, who has been manager of the Ottawa office, will succeed him. D. S. Bell, formerly connected with the Imperial Oil, in Halifax, N. S., has been appointed manager of the Ottawa office.

K. C. Mason, formerly with the Edison Illuminating Co., Brockton, Mass., has been appointed Light and Power Department Superintendent of the Nova Scotia Tramways & Power Co., Ltd., Halifax, N.S., and J. B. Bulley, formerly superintendent of the Tramway department of the Cape Breton Electric Co., Ltd., has been appointed superintendent of the Tramway Department of the Nova Scotia Tramways & Power Co., Ltd., both positions being left vacant by the appointment of M. C. Smith as manager of the Cape Breton Electric Co., Sydney, N.S.

Progress in New Power Equipment

A NEW STOKER

A new mechanical stoker of interesting design, for all grades of bituminous coal and lignite, heads a list of several new products announced by the McClave-Brooks, of Scranton, Pa.

The stoker is equipped with section-top grates having horizontal air space, designed to prevent sifting of fine unburned fuel. The kicker bars are so arranged that in operating there is a complete seal on the heel as well as on the front end of each bar. The kicking movement is automatically controlled, and any kicking position from minimum to maximum can be obtained by a simple adjustment on the front operating shaft. It is also possible to operate the bars in sections, so that any part of the fire can be worked independent of the remainder.

The coal pushers or feeders are operated mechanically, and the length of the stroke is not varied in the usual way, but is kept constant. The interval between feedings is regulated by a specially designed and patented timer, which enables a practically infinite variation of the feeding time.

Coal is fed from side wall to side wall. A pre-heated air arch is used, eliminating the need for special arch brick and supplying the requisite amount of oxygen where it is most needed—in the coking zone—to drive off the volatile gases and eliminate smoke.

The stoker is designed to be driven by steam engine, steam turbine or electric motor, and is equipped with a four-speed gear reduction. In addition, the speed of the driving engine or motor is independently controlled, permitting further variation in operating.

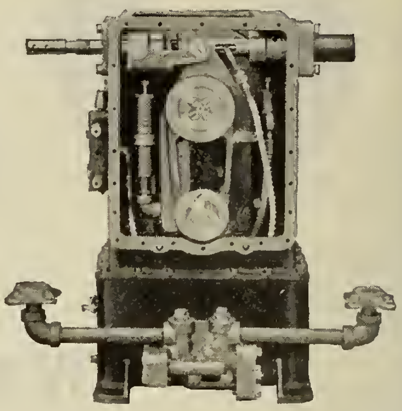
One interesting feature of this stoker is the provision made for hand operation in case of emergency. A clutch disengages the power drive and converts the stoker into a hopper-feed hand stoker in a few seconds, enabling manual operation of the coal pushers and kicker bars. This feature permits the stoker to be kept in service despite power failure of other accident to the mechanism.

A VARIABLE DELIVERY PUMP

The Oilgear Company of Milwaukee has recently perfected a variable delivery pump known as the Oilgear Type W. This pump is designed especially for hydraulic presses and similar service. It has a maximum capacity of 3,060 cubic inches per minute. The maximum working pressure is 1,000 lbs. per square inch.

According to the manufacturer, the flow of oil is steady and free from pulsations. The amount of oil delivered to the press cylinder is controlled by means of a single handle or lever attached to the stroke-changing mechanism through a hydraulically-operated control cylinder. The pump responds instantly and smoothly to the operation of the control handle. This instantaneous response applies both to varying the amount of oil delivered and to reversing the direction of delivery.

The design and construction of the essential parts of this new pump are similar to those in the Oilgear Type QC control pump. These parts include the revolving driver carrying the cross heads and plungers, the cylinder barrel and plungers, the ground ported pintle upon which the cylinder barrel rotates, and the swinging arm by means of which the revolving barrel may be shifted relative to the driver, in order to regulate the length of the pump stroke.

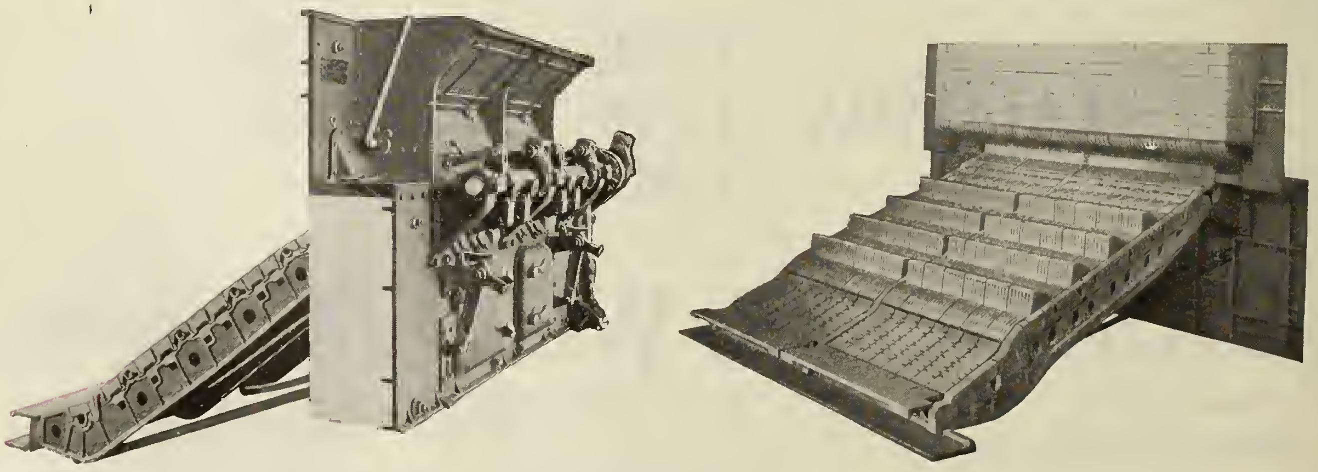


The assembly of the plungers and the cross heads differs from that in the type QC in that the plungers are closely coupled to the cross heads. This provides a suction action that makes it unnecessary to depend on a large auxiliary geared pump. The type W is equipped with a small gear pump to keep the running parts well lubricated and to operate the control cylinder.

The hydraulic control for regulating the stroke of the main pump consists of a double-acting hydraulic cylinder and a piston which is attached to the stroke-changing arm by a cross yoke and two links. These are so arranged that a heavy spring holds the pins at all times against one side of their bearings in the links, cross yoke and arm, thereby preventing any play in the joints.

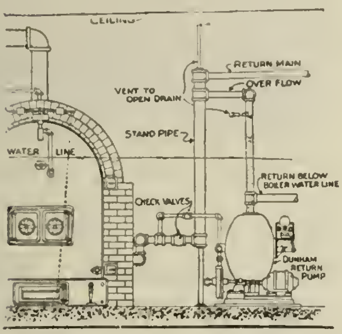
Oil pressure to the control cylinder is regulated by a small balanced piston valve that admits oil to one end of the cylinder and at the same time allows it to flow from the opposite end. This construction provides a hydraulic dashpot which holds the arm rigid in any position.

The oil is delivered from the ports through the passages in the main pintle down through one of the two passages provided in the casting which forms the arm on which the pump unit rotates.



New McClave-Brooks Mechanical Stoker.

Dunham Return Pump
Type R.L.P.
and its application.



The Dunham Condensation Pump is Economical and Automatic

THIS Dunham Return Pump is an automatic, electrically operated centrifugal pump that returns the condensate from heating systems or process work back to the boiler, heater, hot well or other storage.

It eliminates the waste of condensate from heating systems where returns are below the water line and as the return is made as the condensate accumulates improved heating and a saving of fuel result. Being electrically driven, there are none of the difficulties caused by low pressure steam pumps when fires are banked for the night. The Dunham Return Pump operates without attention day and night. It is stopped and started by a float switch.

ELECTRICAL POWER

(Continued from page 36)

penalty, as illustrated in Fig. 1, may reach 15 per cent. of the total bill for electric power. It, therefore, behooves all users to carefully investigate this feature and to see what measures may be taken to correct low power factor.

The remedies available are:

1. Rearrangement of motors, so that any underloaded motors may be replaced by fully-loaded motors.
2. Sell the underloaded motors and install suitably loaded motors.
3. Take out one of the larger underloaded induction motors and install a self-starting synchronous motor and exciter.
4. Install an oil-immersed static condenser, as an adjunct to the equipment.

A great deal may be said as regards these methods, but, briefly, remedy No. 1 has the merit of small cost for re-arrangement, but very few installations will permit of this being successfully carried out; remedy No. 2 has the difficulty that in case, say, 250 h.p. of induction motors are released and sold, and 150 h.p. motors are required, it will be found that, contrary to expectations, a considerable sum of money must be expended.

This is due to the fact that the responsible dealer who buys the motors will necessarily inspect and overhaul the old motors, and as a year's guarantee is expected for the incoming lot of motors (of smaller size) the dealer will charge an appreciable figure for the change.

Remedy No. 3 will generally be found the best all around arrangement. The manufacturers have developed a self-starting synchronous motor, almost as simple as an induction motor, and at a reasonable cost. This motor may be brought to speed by an unskilled attendant or by an attendant who is trained in some process work in the plant, and with no electrical knowledge.

Figure No. 2 shows the relative cost of various types of A. C. motors.

In analyzing such conditions, each case must be taken on its merits, and the services of a qualified engineer are often of advantage to the user.

Miscellaneous

The Canadian Barrels & Kegs, Ltd., Waterloo, Ontario, will equip their dry kiln plant with Jennings hytor vacuum pumps and Armstrong traps.

The Canada Electric Co., 175 King St. E., Toronto, have been awarded the contract for electrical work in connection with the $80,000 addition to the Earl Haig School, Toronto, and the new school being built on Turnberry Avenue, Toronto, at a cost of $100 000, by the Board of Education, Toronto.

H. M. Clark, president of the Clark Gold Mines Corporation, has completed arrangements for the electrification of the Montague Mines, Mount Uniacke, N.S., and other properties which his company recently acquired. A complete plant will be installed at the Montague Mines, and when the work of installing the power to the properties in question is finished, a number of other properties will be operated.

The Sarnia Oil & Gas Company, Sarnia, Ont., has announced that it has accepted plans for a factory to be built at Brantford, to convert natural gas into carbon black. The plant will be of automatic design, and the first unit to be erected will produce approximately two tons of carbon black and 1,000 gallons of absorption gas per day.

In an interim report of the Dominion Fuel Board, regarding the fuel situation in Canada, considerable space is devoted to the supply of peat that could be obtained from the provinces of Ontario, Manitoba, Quebec and New Brunswick. It is stated that out of the 37,000 square miles of peat bog in Canada, 12,000 lie in these provinces and would produce the equivalent in heating value of 5,400,000,000 tons of good coal. The board contends that this peat should be utilized to supply a part of Canada's fuel needs, especially in the Spring and Fall when the maximum of heat is unnecessary.

Comments in the Power Plant Field

LAUDS POWER HOUSE

Power House, Toronto, Ontario.

Campbell Bradshaw, Managing Editor

Dear Sir:—

In reply to your letter of July 26th I wish to say that you have been correctly informed as to our future plans regarding the C. A. S. E.

It is the intention of the present Grand Lodge officers to start an aggressive campaign to increase our membership, also bolster our morale.

The members of the C. A. S. E. in the future will win the esteem of all concerned by meriting it, and to merit esteem we are going to study, in order to advance in our chosen profession, the honorable one of stationary engineering.

Education and more education is our slogan from now on.

We are very fortunate in having as chairman of our educational committee, this year, F. S. Rutherford, organizer of technical education for Ontario.

I wish to sincerely thank you on behalf of the C. A. S. E. for the interest you are taking in regard to our future welfare, and hope to have the pleasure of meeting you in the near future.

I will forward my photo as soon as possible for publication. I certainly would like to meet each and every member of the C. A. S. E., but it is impossible at this time. But I pledge to do my level best to make a greater and better C. A. S. E.

I feel sure that with the help of Power House, yourself, and others, we will make it come true.

I accept your invitation to write your paper every two weeks and will mail a message soon. Enclosed please find cheque for one year's subscription.

With best wishes for the future success of Power House and the C. A. S. E., I am, very truly yours,

JAMES J. SULLIVAN,
Grand President.
20 Jeanne D'Arc St., Hull, Quebec.

EXAMINATION TACTICS

The Editor, Power House:

I was greatly astonished at statements made by the chairman of the Ontario Engineers' Examining Board at the dinner of the Canadian Association of Stationary Engineers, during the recent convention of that organization in Toronto.

J. M. Brown, the chairman of the board, said:

"I am endeavoring through my department to raise the status of the engineers in Ontario by making the examinations of such a nature that the answers will classify the applicants as efficiency engineers."

Continuing, Mr. Brown said: "Last year there were about 8.000 engineers' certificates issued in Ontario, of this number about 70 were first-class certificates, and of the total number who sat for examination, in all grades, about 70 per cent. failed to pass. I was surprised at the number of men who hold British Board of Trade papers, who fail in our examinations.

"You need not worry that there will be a surplus of engineers, as I watch the employment situation, and when positions are scarce for engineers I make the examinations more difficult."

Mr. Brown then went on to state that a good many applicants when writing for information generally want to know how they can obtain an engineer's license. Engineers have certificates, he said, and should treat them in a dignified manner by always calling them certificates, and not licenses.

Unjust to Engineers

I do not think that Mr. Brown is fair, and the above statements, which are the gist of the words he used, prove beyond doubt, in my opinion, that he has been unjust to some engineers.

First, the British Board of Trade certificate is issued to an engineer on his length of service in a machine shop as a mechanic with a certain period at sea, to prove his ability to overcome troubles at sea, as the engineer at sea is more of a blacksmith and machinist than an expert in the chemistry of engineering. The British Board of Trade rules and regulations for engineers are for the upkeep and maintenance of the mechanical side of engineering, and the ship owner like a good many stationary plant owners will see to it in time that the engineers will be more efficient by installing the necessary equipment, for economy, etc.

How very naive Mr. Brown is when he said:

"Do not worry, there will not be a surplus of engineers, as I watch the employment situation, and when there is a scarcity of engineering positions, I make the examinations harder."

Bless his innocence, he forgets that if he makes the examinations harder at one time, then he must make them easier when there is a demand for engineers. Is that fair to the profession? Does it raise the status of an engineer to know there are two sets of examinations, one for good times of employment, which is easy to pass, and another, when employment is scarce, which is harder to pass.

Imagine Bill Jones going to work with his new engineers' certificate, as proud as a peacock of the fact that he had passed the examination for the higher grade certificate, meeting a fireman or engineer that he knows, and saying: "Look at my new certificate, I have just passed for a higher grade. Good for me, eh George"? George replies: "Well, I don't know about that, Bill, I see in the papers that they want umpteen engineers all over the country." Poor Bill!!

This is not fair to the average engineer. The certificate should be issued upon a standard examination that is not governed by the employment situation.

Not a License

Now, in regards to the license being a certificate, and not a license. I would like to point out that the average engineer works long hours, especially those with the lower grade certificates, some working 11 to 13 hours, according to whether he is working in the day time or at night. He goes home when he has put in his hours at work dead tired, a dog's life at work, with a certificate. When he gets home his wife scolds him about his long hours at work, and the marriage certif—, I mean license, becomes a cat and dog license.

Efficiency experts tell us that a man working long hours cannot be efficient, therefore, it seems to me, that the first thing for Mr. Brown's examining board to do is to reduce the hours of the engineer if he wants to make them efficiency engineers. Railroad engineers have stated hours to work, in their rules and regulations. Then, why not the steam and stationary engineer?

The next thing to do is not to fill vacancies by making easy examinations and disappointments, because the pulse of the engineers' labor market is beating low.

In conclusion, it seems to me the engineer's path is by no means a rosy one, if anyone asks me I would say it is full of third rails.—GEORGE A. BROWN,
459 Shaw St.,
Toronto, Ont.

BOILER INSPECTION

Aug. 9, 1923

The Editor,
Power House.

In Power House of June 5, you draw a picture of conditions as they exist in Ontario as regards the inspection of boilers. It is a rather dark picture, but I believe it is true to the facts.

It contrasts very unfavorably with another picture which appeared in Power House on November 5, 1922, by "Inspector."

According to "Inspector" everything was lovely, everybody was satisfied and the country safe.

Laws had been amended as required by the advances in the arts and industries and far in advance of our present industrial requirements. Even the mill owners and factory managers were satisfied and the engineers who usually fig-

POSITIONS WANTED

FACTORY SUPERINTENDENT—OR CHIEF Engineer is open for engagement. Have had wide experience in operating power plants and handling help in Canada. Apply Box 107, Power House.

POSITIONS VACANT

STATIONARY STEAM ENGINEER WANTED—familiar with water tube boilers and Turbo Blowers and Generators. Must be an all round competent man, capable of taking charge of plant of about 2,400 B.H.P. Must have first class certificate. State in first letter salary wanted, age, experience, and when you can report. Apply P. O. Box 720, Port Colborne, Ont.

WANTED — SALES ENGINEER — EXperienced in steam specialty lines. University graduated preferred. Write stating experience and salary. Apply Box 109, Power House.

BUSINESS CHANCES

SMALL BOILER REPAIR BUSINESS FOR SALE—With house property adjoining. No opposition. Located in a large manufacturing city. Reason for selling, owner in ill-health. Apply Box 110, Power House.

TAYLOR SAFE FOR SALE
Inside dimensions 15" deep, 2 ft. 6" wide, 3 ft. 11½" high. We will accept $225.00 for this safe—a bargain for someone. Apply Box 110, Power House.

Stephen's Boiler Feedwater Treatment

Don't endanger your boilers with old-fashioned, expensive methods which are often ineffective. You'll find that the Stephen's Feedwater Treatment is not only more economical but ensures the removal of old scale and prevents the formation of new scale in absolute safety.

Consult our engineers. They are always happy to discuss your feedwater problems in a practical way without obligation to you.

Stephen's Chemical Mfg. Co., Ltd., 2 Johnston St., Toronto, Canada

ure in the mortuary statistics when a boiler lets go, 'weren't doin' any kickin,."

As I have stated that your picture of June 5 is true it must be evident that I do not agree with "Inspector." "Inspector" says that laws are amended as required by advances in the arts and industries. We may assume then that the amendment transferring the inspection of operating boilers from the Steam Boiler Branch to the Factory Inspection Department was intended to be an improvement—that it was expected to result in better enforcement and greater efficiency.

Should Heed Facts

No doubt "Inspector" knows how his department functions and how it has always functioned, and no doubt it was with this knowledge in mind that he stated the law had been amended as required by "advances in the arts and industries."

In Power House of April 5, 1922, there was editorial comment on a fatal accident a short time previously in a Toronto factory. Some facts brought out at the inquest were cited as follows:—"No copy of the factory act had been exhibited in the place for over five years. It was over a year since there had been a factory inspector in the place.

"One factory inspector said the place used to be in his district, and that when it was under his jurisdiction he had ordered guards placed around shafts and pulleys. He admitted visiting the factory after the accident but did not notice whether his recommendations had been carried out or not. The inspector now in charge of the district admitted that he had not made any visit to the place before the accident, giving as his reason the fact that he did not know of the existence of the factory. He stated that when an inspector took over a district he had to hunt out the factories in it, AS THERE WAS NO LIST PROVIDED."

The final paragraph of the report reads: "What seems to be needed is a factory inspection department that will inspect."

"Inspector" At Sea

And "Inspector" wants us to believe that laws are amended as required by advances in the arts and industries. He must think we are as credulous as he would like us to be. Would we be wrong if we inferred in view of the fact that no list was provided, that often when an inspector has just been long enough in a district to become somewhat acquainted with it, he is transferred.

In Power House of April 20, 1922, there is a letter from a correspondent who says, "I think it is about time that the factory inspection department realized that the factory workers of Ontario are entitled to some degree of protection. It is criminal the way the factories of the province are inspected. I was employed by a concern where a new plant was built and put into operation and nearly four years passed before a factory inspector showed up, and then he might just as well not have come for all the good he did. There were a great many things that needed his attention, but all of them went unnoticed by him. What we want are men who are wide awake to the interests of the people employed in the factories of the province and not men who just merely draw their salaries."

Deplores Inspection

What chance has boiler inspection in a department that functions the way the factory inspection department functions? "Inspector" can tell us. I was in charge of my present plant for over four and a half years before I saw a factory inspector in my department.

I am not going to say who prompted the amendment to the Steam Boilers Act, but whoever did it must have known that it was "safe" under the factory inspection department.

If "Inspector" will tell us who opposed the Mother's Pensions Act, the amendment to the Workmen's Compensation Act, and the Minimum Wage Act, and other humanitarian legislation enacted in the last four years, we might be able to guess who prompted the amendment.

As for inspection by engineers, I don't approve of it. Boiler inspection should be independent and impartial, and we can't be sure of impartiality when it is done by "any licensed engineer," as provided by the so-called Inspection Act.

A C. A. S. E. PRESIDENT

C. A. S. E. Notes

At the regular meeting of Kitchener Lodge, No. 9, of the Canadian Association of Stationary Engineers, on Friday evening, Aug. 10, the following decisions were reached:—

That the twin pop safety valve is better than the single, as it is possible to repair one and still have the other one ready for use.

That the size of safety valve for a certain sized boiler is calculated by the formula in the rules and regulations for the construction and inspection of boilers; or, the area of opening should be such that when the boiler is worked at its maximum capacity the steam may escape as fast as it is generated at a velocity of not over 6,000 feet per minute at the working pressure and before expansion.

That the safest position of dampers and doors in blowing tubes in a return tubular boiler with a hand lance is to have the top damper open and ashpit doors closed, because the soot blown would drop to the combustion chamber owing to there being no through draft, also, better results are obtained by having a bright fire.

The second annual week-end excusion and picnic for members and their families was held recently at Port Dover, about 200 making the trip, and a pleasant time was spent at the beach in boating, bathing and sight-seeing. Mr. Turner and family, of the Toronto branch of the association, and Mr. Elles and family, of the Hamilton branch motored down.

Bro. Merritt, president of Kitchener Lodge, No. 9, who is in charge of the mechanical end of the Kuntz Brewery Co., Waterloo, has installed a new water softening system at his plant, and is well pleased with results.

Bro. Eumrich, of the Dominion Button Company, is on the sick list, and has been off duty for the past ten days.

C. OTT, 202 Breithaupt St.,
Kitchener, Ont.

George J. Soucy, Executive Secretary and General Organizer of the Dominion Executive Council of the Canadian Association of Stationary Engineers will go to London, Ont., on Aug. 17, to invest G. F. Galloway with the Past President's Jewel as authorized by resolution of the Grand Lodge on June 28, 1923. A delegation from Woodstock is expected to attend the ceremony, and the annual picnic in Spring Bank Park on Saturday, Aug. 18.

Convention Notes

The entire first floor of the Grand Central Palace, New York City, has been engaged by exhibitors for the second national exposition of power and mechanical engineering, for the week of Dec. 3 to 8, 1923.

The first exposition drew an attendance of 47,580 representative engineers, operating men, and executives, as well as technical students and their instructors.

The conduct of the exposition is supervised by an advisory committee, headed by Irving E. Moultrop, of the Edison Electric Illuminating Company, of Boston. Among his colleagues are John Lule Harrington, president of the American Society of Mechanical Engineers; Calvin W. Rice, secretary of the American Society of Mechanical Engineers; John H. Lawrence, chairman of the 2 Power division of the American Society of Mechanical Engineers; Frank W. Smith, president of the National Electric Light Association, and Fred Felderman, national president of the National Association of Stationary Engineers.

The Electrical Contractor Dealers of Toronto, held a very succesful picnic at Woodbridge on the afternoon of August 8, a crowd of about 400 attending. About $800 worth of electrical goods were contributed by manufacturers and jobbers as prizes for the many races and contests, among them being a vacuum cleaner, handsome table lamps, and many valuable appliances.

Boiler Setting *Service*

THE Gates Engineering Co., Limited, are in a position to contract for and specify on all boiler brick work with the least possible delay. Our Engineering Department is qualified to look after your interests, having made a close study of Combustion Problems.

Our Motto—Service and satisfied clients. The confidence of those who use Gates' Patented Air-Cooled Arch, etc., is unqualified, and is retained, because of the low maintenance cost and the guaranteed results.

Ask for our Descriptive Catalog.

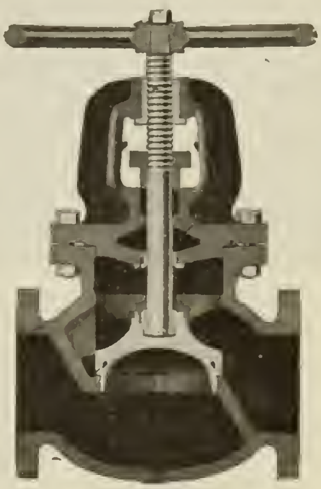
EDWARD *Extra Heavy* Cast Steel Stop Valves

Designed to offer the least resistance to the flow, with full sized opening through seat, with body, bonnet and gland made of Electric Steel and flanges drilled in accordance with American Extra Heavy Standard of 1914, these EDWARD Stop Valves will give satisfaction under the most severe service.



Superior Valves for Exacting Duty

THE EDWARD PROTECTED SEAT AND DISC

This positive protection of the most vital organ of the valve—the seating surface — is used only in Edward Valves. It prevents cutting from wire drawing, especially under high pressures and temperatures where very small leaks rapidly grow owing to the terrific erosion action.

Send for descriptive catalogue of the Edward line.

TRIPLEX DRAFT GAUGE

Gives you accurate knowledge of furnace conditions at a glance. It indicates pressure in wind box, draft in furnace above the fire and draft in last pass.

It is designed and built for convenience of installation, maximum visibility and permanent accuracy. Each instrument must pass the Foxboro quality test.

Write for Bulletin CF-131.

Do You Get 3-Year Service From Fire Brick Linings?

Many firms that have lined their furnaces with jointless Plibrico do. The letters below, received within a month tell the story. If you don't get long service, you need the book "Modern Furnace Building." Write for it.

March 2—Hall Printing Press Co.: "On November 16, 1920, we installed Plibrico under boiler No. 1*** has not required relining since."

March 8—Kinsey & Mahler Co.: "Have eliminated all furnace troubles, since installing this lining, which was put in three years ago."

March 26—Thomas Parisian Dyeing & Cleaning Works: "Lined two 310 h.p. boilers in 1920 with Plibrico****have only had to patch small places."

April 3—Gulf Coast Machine & Supply Co.: "Have not relined our boiler furnace a single time in three years."

April 6—Smith & Wyman Co.: "Have used Plibrico in three of our boilers for over three years."

DISTRIBUTORS: Beveridge Supply Co., Ltd., Montreal; Shell Bar Boico Supply Co., Ltd., Toronto; Evans, Coleman and Evans, Vancouver, B. C.; Winnipeg Supply and Fuel Co., Winnipeg; Building Products & Fuel, Limited, Saskatoon, Sask.; Dominion Lime & Coal Company, Regina, Saskatchewan.

Hays Improved Gas Analyzer.

Are You Wasting Fuel?

Numerous Canadian power plant men correctly answer that question by using the HAYS IMPROVED GAS ANALYZER. Rugged, portable, fast, accurate and INEXPENSIVE, it is the acknowledged leader of Flue Gas Analysis Instruments. Made in two styles. 3-chamber Analyzer for CO_2, O_2 and CO; 1-chamber Analyzer for CO_2 only. Stocked by Canadian Agents listed below.

HAYS DRAFT GAGES, "the fireman's compass," tell him how to regulate his damper, the condition of fires, baffles and settings. Write for your FREE copy of Jos. W. Hays' Treatise on "Drafts and Draft Regulation."

A COMPLETE SERVICE IN

"John Crane"

FLEXIBLE METALLIC PACKING

METALLIC CONDENSER PACKING

This "JOHN CRANE" Process is fully protected by U.S. Patent No. 1,387,901. August 16th, 1921. It is also fully protected by patents in other nations.

The easy application in this process is a marked advantage. Many engineers have told us they consider it easier and faster than fabric packings.

Special pin fits in tube. Packing is pushed into place with hand tool or air gun, then caulked. Illustration shows metallic ring going in.

INVESTIGATE!

Westinghouse, Wheeler, Worthington, Alberger and Elliott and others are now using this process.

Descriptive text (1923 edition) on request.

FLEXIBLE METALLIC PACKING CO.

H. E. CARMAN, 334 Cordova Street, Vancouver, B.C.

No ordinary regulator, and certainly no human water tender, can produce the

RESULTS

that you can get with the

COPES Feed Water Regulator

Every change in the true water level of your boiler is transmitted instantly by the powerful COPES thermostat to the balanced control valve.

We guarantee that every COPES Feed Water Regulator will pass the required amount of water at a given pressure drop. In tests over a 24-hour period, COPES' Regulation has been proved accurate to 1/5 of 1 per cent. In every case, the COPES is carefully fitted to the exact conditions under which the boiler operates.

We will be glad to send you charts, made in actual service, showing how the COPES' smooth feeding is saving from 2 to 8 per cent. in fuel and cutting down labor costs as well. Write for Catalog D.

The simplest and most reliable of boiler feed water regulators—just a rugged expansion tube and a balanced valve.

NORTHERN EQUIPMENT CO.

SYSTEM OF BOILER FEED CONTROL

Makes Short Work of Boiler Scale

In hundreds of plants BOICO has been adopted as the one sure clean-boiler insurance. The speed with which it removes the most stubborn scale formations is surprising. Hurts nothing but boiler scale. It's economical, too.

TRY IT FREE—let us send you a sample to convince you. Write us to-day—you've nothing to lose.

Fostering Economy in the Development of Power for All Industries

POWER HOUSE

Vol. XVI, No. 17 — Published Semi-Monthly by The MacLean Publishing Company, Limited, Toronto, Ont. — September 5, 1923

How Canadian Power Plants are Cutting Ash Removal Costs

Over in Taber, Alberta, the Canada West Coal Company, Ltd., installed an American Steam Jet Ash Conveyor in their mine power house.

Instantly their ash removal costs were reduced 73 per cent. Instead of paying $16.46 per day, for ash handling labor, one man during his spare time now handles the ashes.

Other Canadian power plants are making like savings. Their costs have been cut in half through the installation of American Steam Ash Conveyors. They have paid for their equipment through savings afforded.

A booklet has been prepared describing in detail the ash conveyor system used in these plants. It shows how they were able to cut down their costs in such a remarkable manner.

If your ash handling costs are high—if you are still employing the old-fashioned gang of ash wheelers—if you are using expensively operated mechanical equipment, you will want to avail yourself of the present opportunity to secure a copy of this booklet. It will tell you how to do away with these useless expenditures—how to cut your overheads to the lowest possible figure per ton of ash handled.

The American Steam Ash Conveyors is not an experiment. It is successfully used in 1,500 progressive power plants. Hundreds of letters have been written by plant executives describing the economy and convenience of their equipment and endorsing its use. Solve the ash removal problem at your plant. Take the first step now. Send for the booklet, "Cut Ash Handling Costs." Study it carefully and note the exclusive guarantees which we offer.

The coupon below is for your convenience. Sign it now.

Why It Pays to Store Coal Now!

THERE are five good reasons why every consumer of coal should buy and store his winter's supply of coal NOW.

1—financial advantage
2—assurance of coal
3—better quality of coal
4—lowering coal prices
5—relieving the nation's transportation systems and helping stabilize a billion dollar industry.

Five good reasons, four of which are purely individual and personal. Stored coal really means more money in your pocket—more heat in your fire-box.

How to store coal economically and profitably is something Link-Belt engineers have studied for many years. Let them show you how inexpensively and satisfactorily you can solve your winter's coal problem. Their wide experience and technical knowledge makes consultation worth while.

THE FILES STOKER

Pays for Itself in One Year

Below is a copy of one of the many letters we have received, telling of the efficiency and economy of the Files Hand-Operated Stoker

Re FILES HAND STOKERS

Gentlemen:—

Frequently we receive letters from manufacturers, asking for information and our experience with the "Files Hand Stokers"—the most economical and efficient system of burning coal with the utmost conservation of labor.

As these inquiries are becoming more and more frequent, our better plan will be to furnish you with a letter to pass on, outlining our experience and satisfaction.

In September, 1920, we placed an order with you for two 150 H.P. Tubular Boilers, specifying our desire to have them equipped with "Files Hand Stokers." This we did on the recommendation of our United States Engineering Department, who had installed "Files Hand Stokers" in some seventeen plants, finding in them a decided saving and advantage over flat or shaking grates.

Speaking for ourselves, we have found them most satisfactory and economical, particularly so in regard to the elimination of smoke, rapid disposal of ash and clinker, thorough cleaning of fires without disturbing the active fire, and in maintaining an even bed of fuel.

We are able to keep a clean fire at all times, we have no cleaning period, for with the "Files Hand Stoker" the grate can be cleaned at peak load. It is only a matter of working one rod on each section, which can be done in less than two minutes.

The better the coal the better the result, but almost any kind of coal that will burn free can be used. With good coal, however, it is an easy matter to procure 150% boiler rating, which in reality is 12½ lbs. evaporation per pound of coal. Generally speaking, evaporation is around 7 or 8 lbs., and often as low as 5 or 6 lbs.

Our Files Hand Stokers have now been installed about two years, during which time they have paid for themselves twice over if we consider the saving in fuel.

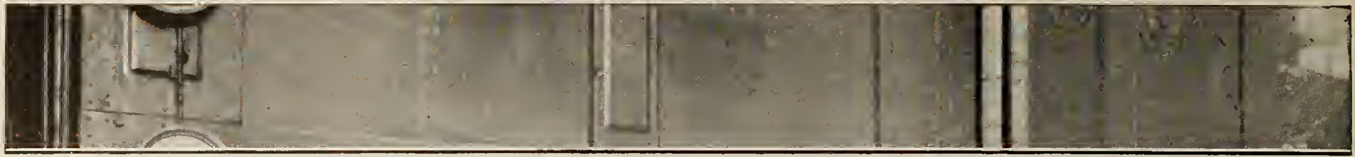
And what we have done and are doing with them others can do.

We know they effect a saving; we know they are a convenience; they have proved satisfactory in every particular, and we have no hesitation in recommending them.

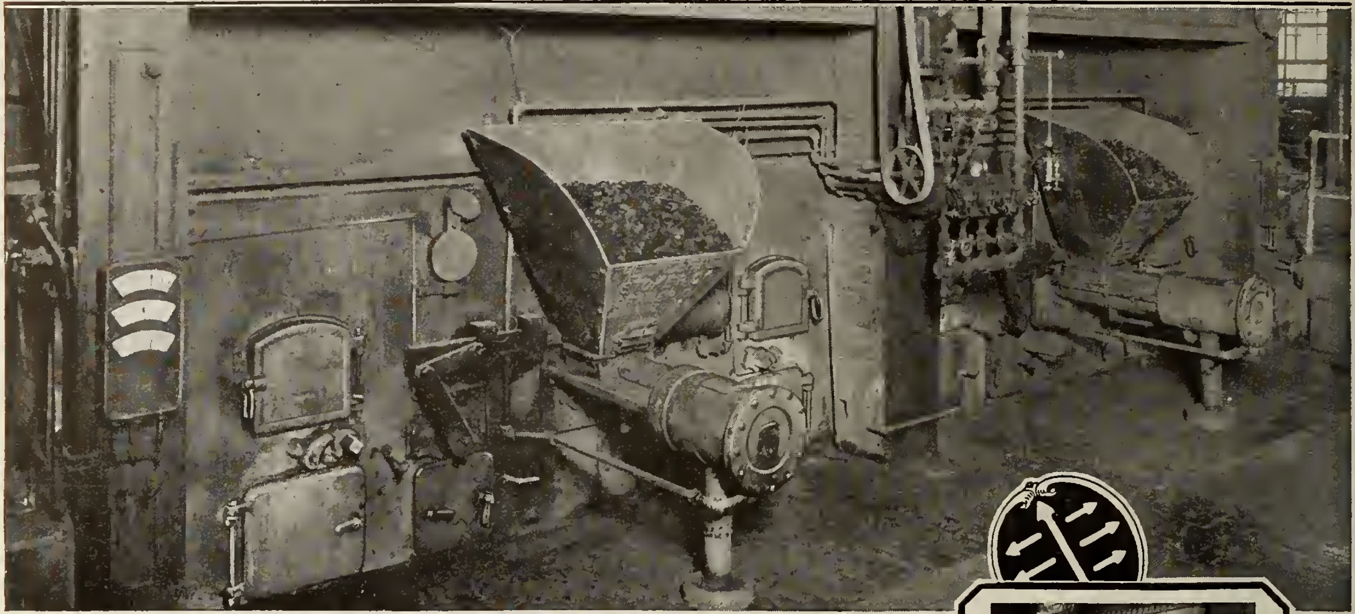
Yours very truly,
THE MERIDEN BRITANNIA CO., LIMITED.

Why not Profit by others' Experience?

Waterous
BRANTFORD, ONTARIO, CANADA



The only multiple retort side cleaning stoker



BEFORE the development of the *"Lateral Retort"* Stoker there was no stoker that combined the ease of installation of the side cleaning stoker with the high efficiency and overload capacity of the multiple retort type. Plants that did not consider the expense of the multiple retort type justifiable were forced to install inferior stokers.

Now the *"Lateral Retort"* has changed all this; now any plant can have multiple retort stoking!

This simple, single retort stoker rivals the efficiency and capacity of the multiple retort type; the illustration opposite and the description below it show how the high duty service of the multiple retort is obtained.

And yet the *"Lateral Retort"* can be installed at a fraction of the cost of a multiple retort. There is no need for basement ash pits; trenches 6 to 18 inches below the floor line are sufficient excavation. This makes the *"Lateral Retort"* easily adaptable to boilers already in service and does away with the maintenance costs of complicated ash discharging and dumping systems.

The new 8½x11 standard filing size bulletin describes this revolutionary stoker in detail—and shows illustrations of successfully operating plants in the United States and Canada. Your copy is ready—ask for it.

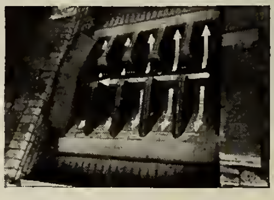
Montreal, Que.



How it works—

IN the **"Lateral Retort"** the coal follows the path of the arrows in the view above. It is underfed to the main retort—along the path of the large arrow—by a simple steam driven ram. An independently controlled moving unit underfeeds the fuel into the **"lateral retorts"** that branch off at right angles from the main retort. The ash is finally deposited on perfectly balanced dump plates easily operated by hand. The ash is dumped into shallow ash pits 6 to 18 inches below the floor line.

High air cooled front and rear tuyere blocks keep fire and clinker away from the front wall and bridge wall, practically eliminating clinkering and reducing furnace maintenance. Plate tuyeres that form the sides of the retorts reduce sifting and lower replacement costs.

Keeping Tabs on the Man who keeps Tabs on Temperature

The addition of a Time Punch device on Columbia Recording Thermometers eliminates spoilage and losses through careless inattention to the maintenance of uniform temperatures.

It gives absolute assurance that the man in charge of temperature control will inspect the chart at specified intervals. If he fails to push the button as instructed, the absence of punch holes on the edge of chart will show that he has been delinquent.

An operator can't be careless or neglectful and get away with it. The Time Punch trips him up every time. It is strictly impartial. When a man is a good worker, conscientious and careful, it gives him credit for it. If he's lazy, and inclined to be asleep at his post, the boss knows all about it.

Thus does the Columbia Recording Thermometer, with the new Time Punch and its day-and-night indelible record of temperature, insure uniform temperatures. And that means lower operating costs, less spoilage, greater efficiency. Two wonderful instruments in one for the cost of one.

Columbia Recording Gauges and Tachometers are also equipped with the Time Punch.

UNDER ideal conditions, with plungers smooth and absolutely in line, the prevention of leakage at stuffing-boxes, when handling extremely hot water at high pressures, presents a definite problem.

When plungers are scored and out of line, a packing especially designed for such service will be found in Garlock Style No. 443 combination. This packing will prevent leakage and give lasting satisfaction; the rubber cushioned flax and diagonal rings reacting to any lateral movement of the plunger with minimum friction.

Try Style No. 443 on your feed pump plungers.

JENKINS

Extra Heavy Iron Body Globe and Angle Valves

Maximum strength and rigidity are rigorously preserved throughout in the design and construction of Jenkins Extra Heavy Iron Body Valves. This reserve strength amply meets the strains and stresses due to expansion and contraction of piping or other causes.

These valves are suitable and guaranteed for 250 pounds working steam pressure, or 400 pounds working water pressure—the margin of safety is wide, for each valve before it leaves the factory is tested to 800 pounds hydraulic pressure.

The bodies of these valves are made of high-grade cast iron; the spindles are manganese bronze, having a tensile strength from 50,000 to 60,000 pounds per square inch. Regrinding discs and seat rings made of durable steam metal.

YORK MECHANICAL REFRIGERATION

The Key That Unlocks the Door to INCREASED PROFITS

THOUSANDS of York Machines have paid for themselves, and are now earning substantial dividends for their owners. These machines are designed for service, built of the best materials for the purpose, thoroughly tested and rigidly inspected before shipment. They are self-contained, require very little attention and do not require a skilled operator. There is probably no other equipment you can buy that will be a greater help in increasing your profits than a York Refrigerating Machine.

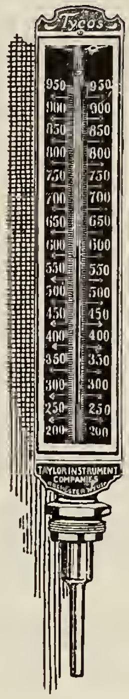
Tycos and Superheat



The degree of superheat may be determined at any time during the operation by glancing at a *Tycos* Superheated Steam Thermometer. A record of the performance of superheaters can be placed on your desk every day if a *Tycos* Bi-Record Recording Thermometer is used. This Recorder gives both the pressure and temperature of the superheat on one chart. The chart shows the amount of pressure and temperature simultaneously.

On exceptionally long superheated steam line *Tycos* Bi-Record Recording Thermometers (or *Tycos* Superheated Steam Thermometers) will show the amount of temperature loss due to pipeline radiation and also drops in pressure.

Small Compressors for the Modern Industrial Plant

The small compressor for machine shops, foundries, or other industrial plants, should be efficient, reliable and as nearly automatic in action as modern design and skilled workmanship can make it.

Efficient because so many operations require air and the lower the cost of compressing air, the greater the saving in production costs.

Reliable because if the compressor breaks down production will be held up until repairs can be completed.

Automatic because usually but little attention can be given the compressor; labor is generally scarce and costly and an operator's time can often be used to better advantage in other ways.

For this class of work there is no simpler or better machine than an Ingersoll-Rand Class ER or FR Compressor.

You can always satisfy yourself as to the value of these machines before buying, as it is easy to locate nearby installations where their worth is being constantly proven.

Class ER and FR Compressors are straight line, single-stage, double-acting units fitted with Ingersoll-Rand Plate Valves. They are simple, sturdy machines possessing every requisite for efficient and continuous operation with minimum care and attention. Class ER units are furnished for long or short belt drive; Class FR machines are equipped with piston steam valve and automatic cut-off flywheel governor. They are readily converted to belt drive if desired.

When operations demand more air, additional ER or FR units may be installed, resulting in a very flexible plant. If a larger compressor is preferred, they can be used as auxiliaries, or readily sold at a price which will help materially in buying the larger machine.

Our nearest branch will be glad to help you select and get the most out of pneumatic equipment for present or contemplated needs. Consult them whenever they can be of service.

INSURING SAFE HIGH PRESSURE PLANTS

Meeting the need of the modern power plant for piping equipment to handle high pressure superheated steam, Crane Ltd. has produced a complete line of valves, fittings and steam specialties of cast-steel and monel metal. The use of these materials overcomes the "growth" or permanent expansion encountered with cast iron, malleable iron or semi-steel units which are subjected to wide temperature variations. Crane cast-steel equipment retains its original size and strength under the most severe conditions, insuring permanently tight connections and maximum safety.

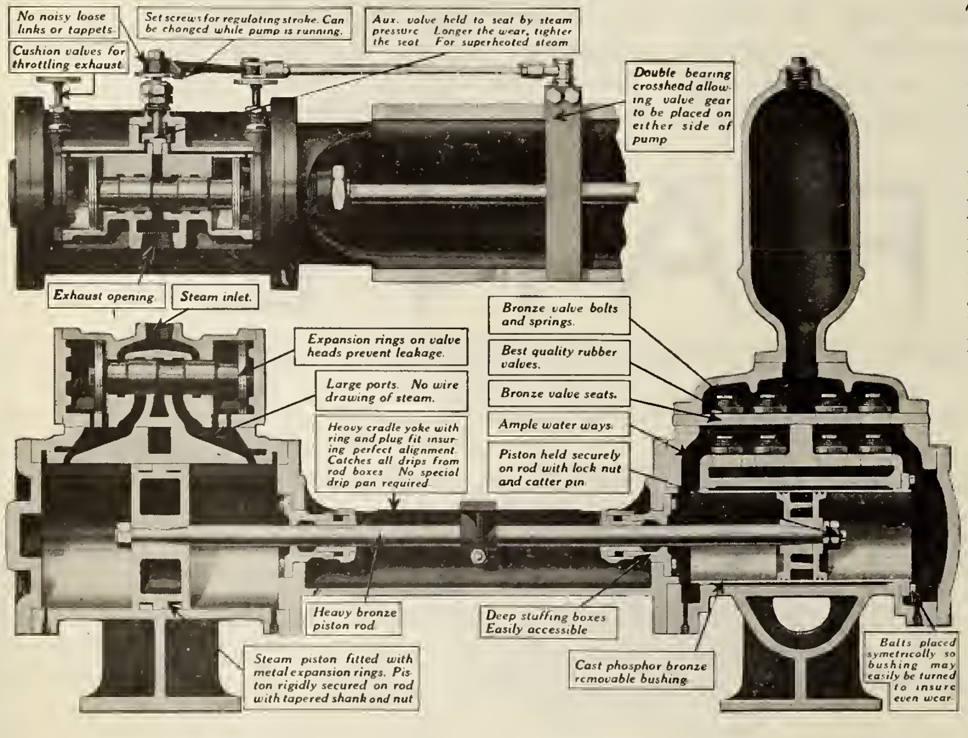
AMERICAN--MARSH PUMPS



No noisy loose links or tappets.
Set screws for regulating stroke. Can be changed while pump is running.
Aux. valve held to seat by steam pressure. Longer the wear, tighter the seat. For superheated steam
Cushion valves for throttling exhaust.
Double bearing crosshead allowing valve gear to be placed on either side of pump
Exhaust opening.
Steam inlet.
Bronze valve bolts and springs.
Expansion rings on valve heads prevent leakage.
Best quality rubber valves.
Large ports. No wire drawing of steam.
Bronze valve seats.
Heavy cradle yoke with ring and plug fit insuring perfect alignment. Catches all drips from rod boxes. No special drip pan required.
Ample water ways.
Piston held securely on rod with lock nut and catter pin.
Heavy bronze piston rod
Deep stuffing boxes Easily accessible
Steam piston fitted with metal expansion rings. Piston rigidly secured on rod with tapered shank and nut
Cast phosphor bronze removable bushing
Balts placed symetrically so bushing may easily be turned to insure even wear.

THE illustration tells its own story. Why the American-Marsh are the most reliable, trouble-proof and efficient pumps on the market.

Less than one-half the wearing parts found in the duplex type while a saving of 25% in steam consumption is guaranteed.

Over 160,000 in successful operation.

Guaranteed Blow-Off Service

Put Yarway Tandem Blow-Off Valves in your plant and for two years, at the very least, you won't have to spend another cent for blow-off service.
The Yarway Tandem—a combination of the Yarway Seatless Blow-Off Valve (formerly the Simplex) and the Yarway Double-Tightening Valve—is **unconditionally guaranteed** for two years. Should any part of either valve fail within that time, we'll make it good.

The chances are about fifty to one that you'll get much more than two years' service from the Yarway Tandem. The Yarway Seatless has established many records of eight and ten years' service, often without repairs; and the Yarway Double-Tightening —the younger member of the tandem—is building up similar records for itself.

Both valves are described in Booklet B-410. May we send you a copy?

CAMPBELL BRADSHAW, Managing Editor

N. C. SHATFORD
News Editor

Sharing Real Savings

COMPLAINT was made at the Canadian National Exhibition in the past week, by the owner of a large Quebec plant that engineers do not co-operate wholeheartedly with the management in cutting fuel costs in power plant operation but seem to think that their sole duty is to keep up the required pressure.

This accusation is unfair to the great majority of the engineers of Canada, but if it is true that some engineers fail to realize that they are a part of an organization primarily concerned in earning a return on the capital invested and do not co-operate with the management to that end, is the fault entirely with the engineer?

How many owners show appreciation of the efforts of their engineers to cut down labor costs and prevent waste of coal, oil and other supplies.

Too many accept such savings as a matter of course and it seldom occurs to them to give the engineer even a word of thanks, much less show their appreciation in more tangible form.

Conscientious engineers, with a proper pride in their work, whether it receives recognition or not, will nevertheless continue to give the best possible service they can render, although it may be true that sometimes they cannot help but harbor a feeling of resentment that their efforts on behalf of their employers go unrewarded, when their records clearly show that a saving of thousands of dollars a year often has been effected.

It must not be forgotten that some of the larger and more progressive manufacturers seek to create a personal interest on the part of their engineers by paying a bonus in recognition of economies effected, but although the practice is gaining momentum daily it is not yet by any means general.

Those enlightened managements, which recognize that the engineer is entitled to a small percentage of what he saves, are not the ones who complain of lack of co-operation on the part of their employees.

* * * *

Power, Heat and Light

REAL ability is necessary when the engineer is called upon to determine the proper distribution of power in a plant. Suppose his problems involve the proper capacities of electric, steam or water lines, as related to distances covered, average and peak load conditions, and various applications of such energy to present and prospective production units and their necessary requirements.

He must see that present needs are provided for, and also are sufficient to carry the increase needful to probable development.

What horse power should be provided for a given unit? Is it one of a group of similar units? What percentage of time are all such units operated at once? Are other kinds of machines likely to be idle while these units are operated?

Answers to questions like these are not only of real importance, but their practical application may well mean increased boiler capacity and power made available elsewhere in the plant, where a congestion might otherwise interfere with normal output.

Heating and lighting are closely allied to power as regards distribution; in fact, all the elements which go to make for proper manufacturing conditions are of so great an import that it is vital to-day for the engineer to obtain from reliable sources such as Power House the data and experience that permit him to understand fully their relation to one another and to power in these days of progress.

* * * *

An Anthracite Strike

ONE indictment of present day civilization by the 158,000 men engaged in the anthracite industry, is that facts vitally affecting the coal problem are ignored by the public. To a large extent any decision as to "full recognition," hours or wages is a game of blindman's buff—blindman's buff tempered by force and necessity.

Here is a basic industry—the very flame of life in many of the homes of Canada under existing conditions—and yet have we sought to know it, to master it, in a sensible and fore-thoughtful way to avoid being trapped by our dependence upon it?

Or is it accurate to speak of "chaos" as the truth—that we ignore the fact that storage is to the coal industry what the fly-wheel is to an engine.

Continuous operation must be the fundamental aim of any successful enterprise. Perhaps some day we may consider it the paramount aim. Intermittent operation breaks down the morale of a working force, leads to high overheads, prohibitive price quotations and failure to meet quantity and quality standards in the product. Then, too, intermittent operation is usually accompanied by an unbalanced wage scale and unnecessarily high hourly and piece rates which make but a poor substitute for a high annual return to the workers.

It should be recognized that this irregularity of operations is the primary cause of the unsatisfactory condition of the mining industry, the high prices of coal and the dissatisfaction among the miners and operators alike.

Regularity of operation necessarily involves regularity of demand whether the product be mined in Alberta or Pennsylvania, and it is possible to accomplish much in this direction through stimulation of demand in the seasons which are normally dull, and by discouraging orders at the peak.

* * * *

Send in Your Picture

IN THE next issue of Power House there will be the usual number of articles, practical ideas and newsy notes of what men in the power plant field are doing. Each article and idea is supposed to contain one thought that is of interest or of value in cutting operating costs.

Speaking of things of interest, why don't you send in an odd picture of yourself, or a picture of something you have done? It's so easy to send a photo or a snapshot, with a line or two on the back telling what it's all about.

Your picture will be welcome. The more pictures the better the Power House

Why Labor Decides Use of Coal or Oil As Fuel

Specially written for Power House

Consensus of Opinion Indicates That Oil at Five Cents a Gallon and 14,000 B.t.u. Coal at $8.72 a Ton is Same Price per B.t.u. Turned Into Steam

> *In our heating plant we have two boilers of approximately* **100** *h.p. each. One is fitted with an oil burner and last year we used oil in it to heat our building, the consumption being 48.000 gallons approximately, which ran our costs up pretty high. As a result we are considering the use of coal this year. Which is the cheaper fuel for our plant if it is necessary to employ two extra men to do the coal firing?*
>
> —HERBERT BALL, Toronto.

IN DECIDING whether fuel oil burning equipment is more economical than coal burning equipment in the average plant, the writer has found a large number of what might be called major considerations. The following list is by no means complete but may be suggestive to those faced with this problem:

1. The fuel cost per boiler horsepower hour at the existing contract price for coal and oil.
2. The dependability of the supply of each.
3. First cost of the boiler burning equipment proper, repairs, and replacements, depreciation.
4. The fuel storage problem and fire hazard.
5. Relative labor costs.
6. Ash handling and removal.
7. Cleanliness.
8. Flexibility in meeting sudden changes of load.

In the above tabulation no attempt has been made to place the factors in order since their relative importance depends almost entirely on local conditions.

Average Evaporation

First is the balance of the B.t.u. against dollars' worth of fuel. For example, let us assume that a plant burns 14,000 B.t.u. bitumionus coal in hand-fired boilers. In units where the load curve is not too regular, an equivalent evaporation from and at 221 deg. Fahr. of 8 lbs. of water per lb. of coal, should be averaged.

The corresponding figure for well installed oil burning equipment is an equivalent evaporation of 13 lbs. of water per lb. of oil. The coal, let us say, cost $6.00 per ton of 2,000 lbs., while the oil price has been quiescent around 10 cents per gallon for tank delivery.

Based on these values, the fuel cost per boiler h.p. hour is:

For bituminous coal 1.3 cents
For fuel oil 3.78 cents.

Another way to say this is that oil at 5 cents per gallon and 14,000 B.t.u. coal at $8.72 per ton is the same price per B.t.u. turned into steam. The comparison is often between oil and stoker-fired coal. If the small stoker-fired plant is well managed, an equivalent evaporation of 9½ lbs. might be expected. In this case the fuel cost per boiler h.p. hour is reduced to $1.09 cents.

Coal at $8 a Ton

Assuming that steam coal is delivered to the boiler room of the Toronto plant in question at a cost of $8 a ton in September, and that the heating value of this coal is 13,000 B.t.u. per lb., and that fuel oil can be bought at 10 cents a gallon, with a heating value of 19,000 B.t.u. per lb., and a weight of approximately 9 lb. per gallon, then the cost of the 48,000 gallon of fuel oil used in the season would be $4,800.

The actual heat contained in this oil (48,000 x 9 x 19,000) B.t.u.

The heat contained in one ton of coal (2000 x 13,000) B.t.u.

The tons of coal equivalent to this would be

$$\frac{48\,000 \times 9 \times 19{,}000}{2\,000 \times 13{,}000} = 316$$

Assuming that oil can be burned with an efficiency of 75 per cent., and coal with 60 per cent., then to equal the heating value of the oil actually $\frac{75 \times 316}{60}$ =395 tons of coal would be necessary.

Cost of coal then is 395 x 8 =$3,160.

If coal were used, two firemen would be required, working 12-hour shifts, 7 days a week. If the rate for firemen was 45c. per hour, and they were required thirty weeks a year, the labor bill would be 45 x 24 x 77 x 30 =$2,268.

Cost of coal—$3,160 + 2 268 =$5.428.
Cost of oil — $4 800.

Difference in Cost

The difference in cost assuming oil at 10 cents per gallon, and coal at $8 a ton, and that two more men are necessary utilizing coal, is therefore slight.

Now let us consider this problem from the viewpoint of a plant in pre-war days close to the Pennsylvania coal fields utilizing 7 water tube boilers rated at 1,650 h.p., which considered the alteration of its boiler room to burn liquid fuel.

The figures given apply fairly well to a plant in any section of the country when the proper substitutions are made for present prices of coal and liquid fuel.

In the plant under consideration the seven boilers supplied steam 24 hours a day at 125 pounds pressure. A mixture of 85 per cent. No. 3 Buckwheat and 15 per cent bituminous coal was being hand fired, the cost of the mixture being $5.00 per long ton delivered at siding.

A fuel oil contract was offered at 3 cents per gallon f.o.b. siding. The oil weighing 8 pounds per gallon. Calorimeter tests of the fuels under consideration were as follows: (dry)

	B.t.u. per lb.
No. 3 Buckwheat	10,900
Bituminous	13,900
Mixture (85% and 15%) ..	11,350
Fuel oil	18,500

Increasing Efficiency

An efficiency of 62½ per cent had been regularly obtained with coal. It was assumed that under oil the efficiency of the boilers would increase to 67½ per cent., since uniform fire would be possible, and the doors need seldom be opened for cleaning the fires.

The average daily equivalent evaporation from and at 212 degrees Fahr. for this battery of boilers was 1,141 000 pounds of water.

In this study all the fuels were assumed to be dry when burned. The number of heat units actually transferred into the water was for the two kinds of fuel as follows:

Coal mixture 11,350 x 62½ / 100 = 7,094 B.t.u.
Fuel oil 18,500 x 67½ / 100 = 12,487 B.t.u.

The number of heat units necessary to raise 1 pound of the water (equivalent evaporation) into steam is 974.7.

Therefore, the number of pounds of each kind of fuel necessary per day will be:

Coal

$$\frac{1{,}141\,000 \times 974.7}{7{,}094} = 157{,}000 \text{ pounds}$$

Fuel oil

$$\frac{1{,}141{,}000 \times 974.7}{12\,847} = 86\,6000 \text{ pounds}$$

The daily cost of each kind of fuel will be:

Coal

$$\frac{157{,}000 \times \$5.00}{2{,}240} = \$350.$$

Fuel oil

$$\frac{86{,}600 \times 3c}{8} = \$325.$$

There was then a slight saving at this price of nine years ago in fuel cost for fuel oil over coal. In the comparison of daily boiler room costs for the two types of fuels, however, the cost of labor, water, supplies and repairs had to be considered similarly to the Toronto plant to-day.

1 Ton and 154 Gallons

It is of interest to note, by comparison of the pounds of coal and oil necessary per day, that under conditions outlined one ton of the coal mixture was equivalent to 154 gallons of oil.

Comparative fuel and labor costs were then per day as follows:

Coal		
Fuel cost		$350.00
Labor cost		
Firing and coal passing	$84.14	
Repairs	13.29	
Handling ashes	7.38	
Handling coal in	13.68	
Ash removal	13.68	
Supervision	3.62	
		135.79
Total		$485.79

Fuel Oil		
Fuel cost		$325.00
Labor cost		
Firing	$30.09	
Repairs	9.30	
Supervision	3.62	
		43.01
Total of fuel oil		$368.01

The daily saving of fuel oil over coal was about $120. or 25 per cent of the total fuel and labor cost when using coal.

Changing Over Costs

Having established the possible saving through the use of fuel oil at 3 cents a gallon, the cost of changing over to burn liquid fuel was of immediate interest. This cost was estimated roughly as follows:

Oil circulation systems, pumps, burners, installed ready for operation but without storage tank and small preheating tank: $1.00 per rated b.h.p., total $1,650.

Storage tanks holding 10,000 gallons, or ten day's supply, together with small circulation and preheating tank of 1 000 gallons capacity, $5,000 installed, or about $3.00 per rated b.h.p.

Assuming the price of coal would not drop materially in the near future, and that an oil contract could be signed for several years at the price named. it was decided to change over the boilers to fuel oil. The actual cost of the conversion turned out to be:

1,700 fire-brick @ $70 per 1,000	$539.
1,400 lbs. high temperature cement	30.
Portland cement and fireclay	35.
Mason's labor	336.
Pipefitters' labor	150.
Cost of two pumps and pipe	350.
Strainer	15.
Fourteen burners	210.
Circulation and preheating tank	250.
	$1.915.

In Canada to-day with an oil price of 9 cents a gallon, the best obtainable, and steam coal quoted at $6.38 f.o.b. cars a very different condition prevails in the heating of large units, the use of oil being almost prohibitive, as fuel oil with a gravity of .9 and a heating value of 19,000 B.t.u. per lb. costing 9c per lb. is equivalent in cost solely on a B.t.u. basis, to 13 000 B.t.u. coal costing $13.70 a ton.

Reads Power House—Wins Wage Boost By Reducing Fuel Costs Thirty Per Cent.

By C. RYE*

WHEN our coal bin was filled with a lot of slack coal. which resembled black sandy mud more than it did a pile of latent heat, we tried several ways to induce it to burn and let us have the heat which it possessed, which was not much, to put it mildly.

The coal was like so much black sand, and it caused our firemen to say a few things that would not look good in Power House. The coal was bought through the office, and to many offices anything black that a coal dealer calls coal, is coal.

The engineer tried all possible ways to burn the stuff, but was not making much progress, when he asked the around him if they had ever seen, heard, or read, of any method of burning material such as this so-called coal! Much to his surprise, one of them had a recollection of reading in his engineering newspaper about a fellow who mixed such stuff with sawdust and got good results.

This gave a ray of light to the engineer. Hope dawned, and he speedily obtained a load of dry sawdust which he mixed with the coal until he got a mixture that seemed to make the old boilers groan with heat.

This mixture was tested to see why so much heat was developed, and the following conclusion was reached:

Lacked Air

When the slack coal was fired it checked the fire, as the smoke given off from the new coal could not get enough air through the bed of fine coal. This made a lot of smoke and combustion was not completed, such a condition wasting most of the coal that did burn.

Any attempt to work the fire, so as to get more air through the bed, resulted in allowing slack coal to fall through the grates.

The sawdust brought the following result, when mixed with one part of sawdust to two of coal, by volume. When fired first, the usual gas and smoke was given off by the coal, but as sawdust gives off a gas that ignites at a temperature much lower than coal gas does, this gas consumed the coal gas and smoke, causing the firebox to be full of flame as long as the sawdust lasted.

Then the fire was hot enough to drive off and completely burn the coal gas, which continued the flame and heat, and as the sawdust that was in the bed of burning coal was heated so that it was gasified, as about all that takes place in a furnace is to gasify the fuel, and then ignite it and see that combustion is completed—and as this gas comes in contact with the flame and air, combustion was completed.

This left the place that once held the particles of sawdust practically empty, and as the coal bed then resembled a sponge, it was easy to get air through it.

Holes Grew Larger

As the coal burned, these small holes grew larger, admitting more air. but the bed of fuel held its form much better than was expected. This allowed fresh fuel to be applied with less trouble in keeping the fire bed free from hills, hollows or holes.

This bed of coals or coke needed little or no working. As everything was naturally taking care of itself, the fire burned clear, the smoke was consumed, steam was up, and, best of all, the engineer was back where he generally is when everything is O. K.

If you want to see what happens when sawdust and coal are fired, take a handful of slack coal, slightly dampen it and shut your hand tight on it. It will stay in a lump as you compress it. Now mix sawdust with it and try squeezing it again, and when you release it it will fall apart.

This indicates an opportunity for air to work its way through the fire bed and help support combustion, which is impossible in the first case where the coal is "tight."

When such good results were obtained more sawdust was ordered at once at a cost averaging three cents a cubic foot, and weight for weight it was as cheap as coal on a B.t.u. basis. But the mechanical mixture of the two solids and the chemical mixture of the two gases sure did make the engineer and all hands smile.

Still Better Results

After the coal was all burned, we got a different kind of slack coal at a much lower price and mixed it with the sawdust, and even better results were had for still less money.

The extra work for the fireman did not amount to the time needed for firing with the coal alone, but as there was a thirty per cent. saving in fuel expenses, each operator involved received an increase of twelve dollars and fifty cents per month.

This was recognition from our employer of his willingness to share with us the profit of our improvements, and he was as well if not more pleased than the engineer.

I have more to write along similar lines, but would rather wait to see if this is printed in Power House, the paper that has been such a helping hand to engineers in time of need.

I often sit and wonder, would we be in the same old rut instead of enjoying better conditions in life if our sawdust suggester had been a fellow who did not read papers such as Power House to see how the other fellows overcame their difficulties?

---

*Wesley College, Winnipeg, Man.

London No. 30, Canadian Association of Stationary Engineers, on frolic at Springbank Park, London, Ont., on Aug. 18.

Rain Fails to Mar Fun of London No. 30, C.A.S.E.

G. F. Galloway, Immediate Past President of Association, Given Jewel by Geo. J. Soucy, Dominion Secretary—Mrs. William Ward Crowned Queen of Beauty

"I SURELY did have a good time!" This seemed to be the way members and friends of London No. 30, Canadian Association of Stationary Engineers had of expressing themselves on August 18, after the annual picnic of the association at Springbank Park.

The spot chosen for the picnic was certainly one of the prettiest possible, about four and a half miles west of London on the banks of the Thames river. The weather did not fulfil its early morning promise, for about 3.30 p.m. the exact hour the sports were scheduled to commence, rain began to fall, and for a while thoughts of a flood were paramount. Nothing daunted, however, George Moll, president of No. 30 and chairman of the sports committee decided to reverse the programme, and gave the ladies orders about the preparation of supper. In due time the signal to "fall to" came, and Mr. Moll urged members and others to make themselves at home, though even as he as speaking, he admitted that all present eemed to be doing that very thing.

About 5.30 p.m. the rain held up ufficiently long to enable a group photograph to be taken, and after everyone had "smiled" at the camera the presentation of a past president's jewel was made by the grand secretary of the Association, George J. Soucy, Toronto, to G. F. Galloway, immediate past president of the association.

The sports programme was varied, and certainly tested the prowess of all ages and sizes. Among other amusements, a beauty contest was held, and after long deliberation—for it was no easy matter for the judges—Mrs. William Ward was declared the victor. Miss Shirley Ward, daughter of Mrs. William Ward, was voted the prettiest child present. The youngest aspirant for membership in the C. A. S. E. was William Potter, six months old son of Mr. and Mrs. Albert E. Potter.

About the most popular pastime was the watermelon eating contest, during which George Moll proved himself to be an able entertainer. He sang many southern melodies and other popular airs, among favorites being "Shufflin'," "How Wet I Am," and "Pack up your Pleasures in your old Dinner Pail."

After supper an attempt was made to carry out the original programme insofar as the ball game was concerned, but only one inning was played, which showed a score of 13 to 2. Woodstock, represented by a large delegation, made up one team, and picked men from London played on the other. R. A. Lyons, of the Garlock Packing Company, acted as umpire on all disputed points, and the players realized after one or two attempts, that it was quite useless to gainsay his decision.

The line-up was as follows:

Woodstock team—R. Arnup, captain; Fr. Ferguson; Art Gepp, sr.; Art Gepp,jr.; H. Argent; William McCalley; Ed. Wilcon; K. McCalley; W. McFadden.

London team—J. Smith, captain; V. Whittaker; D. F. Campbell; G. F. Galloway; J. Waters; G. E. Moll; D. Freedy; J. Reynolds; W. Baker.

Grand Finale Staged

At 8.15 p.m. the grand finale was staged, consisting of a "penny scramble" for the kiddies. Needless to say, all entered, though all were pretty tired by this time. Amy Stevens proved the smartest and was rewarded by becoming the owner of the wherewithal to keep her in lollipops for quite a few days.

The following is a list of the races and their winners. The winners are residents of London except where otherwise stated:

1. Boys under six years—first, E. E. Stevens.
2. Girls under six years—first, Shirley Ward.
3. Boys ten years and under—first, Chas. Darman; second, Sidney Nash; third, Bert Potter.
4. Girls ten years and under—first, Evelyn Gepp (Woodstock); second, Marion Ash; third, A. C. Steven.
5. Boys fourteen years and under—first, Chas. Darman; second, Sidney Nash.
6. Girls fourteen years and under—first, Grace Clark; second, Evelyn Gepp (Woodstock).
7. Single Men's Race—first, Ed. Wilcox; second, Ken Smith.
8. Single Ladies' Race—first, Florence Galloway; second, Emily Tripp (Woodstock).

Expressions of regret were heard on all sides on account of the departure of Mr. and Mrs. G. F. Galloway from London to Galt, Ont., and hearty wishes were extended for Mr. Galloway's success in his new venture. He has purchased a controlling interest in a motor sales business in Galt, and will still maintain his interest in the C. A. S. E., and will attend the convention to be held next year in Montreal.

Thus ended a wet, but very enjoyable day. The children were tired, as children should be after a picnic, but it is unlikely that the day will be forgotten for some time to come. When the C. A. S. E. does anything it does it with the utmost success.

Combustion Losses and How to Minimize Them

By ROBERT JUNE, A.S.M.E.*

The Place to Begin to Save Dollars in Power Plant Operation is the Boiler Furnace—Here There is Opportunity to Effect Larger Savings Than Anywhere Else

COMBUSTION is supported solely by oxygen and a combustible therefore is an element or compound which will combine with oxygen. Table 1 comprises the principal elements and compounds encountered in the combustion of coal, and shows the chemical reactions which take place. The ignition temperatures of the combustible constituents of the coals commonly used in boiler practice are also given in Table 1.

Air, a chemical mixture of oxygen, nitrogen, and slight traces of carbon dioxide, water vapor, argon, etc., is for the purpose of combustion considered to be proportioned as follows:

	By Volume Per Cent.	By Weight Per Cent.
O_2	20.91	23.14
N_2	79.09	76.85

The nitrogen in the air is a source of direct loss in combustion since it absorbs heat in its passage through the furnace. It is a further source of loss since space must be provided in the furnace, boiler passages, and chimney for its accommodation, which would not be required if pure oxygen could be supplied to the fuel.

B.t.u. Value of Elements

The B.t.u. value of the various elements and compounds listed in Table 1 is given in Table 2. This table shows vividly the difference in heat produced between burning one pound of carbon to carbon monoxide, (CO), and burning the same carbon to CO_2. Nearly three times as much heat is produced in the latter case. High production of CO_2 then is essential to high combustion efficiency.

In studying Tables 1 and 2 it is well to remember that the heat value in the boiler furnace is dependent upon the final products of combustion, and that intermediate combinations which may have occurred, have no bearing upon the ultimate result.

Air for Combustion

The terms "perfect combustion" and "complete combustion" are frequently confused. Perfect combustion would result if all of the elements and compounds in the fuel were to be combined with oxygen which would be supplied in such proportions that all of the oxygen would be utilized.

In distinction from this, complete combustion results from the oxidation of all of the elements and compounds, but it does not imply that all oxygen supplied is utilized. With "perfect combustion" there would be no boiler losses. With "complete combustion" boiler losses occur because of the presence of excess oxygen.

TABLE I

ELEMENTS AND COMPOUNDS ENCOUNTERED IN COMBUSTION

Substance		Atomic Weight	Molecular Weight	Reaction	Ignition Temperature Degrees F.
Carbon	C	12	—	(to CO) $2C+O_2=2CO$ (to CO_2) $2C+2O_2=2CO_2$	(Fixed Carbon Bituminous) 766 (Fixed Carbon Super Bituminous) 870 (Fixed Carbon Anthracite) 925
Carbon Monoxide	CO	—	28	$2CO+O_2=2CO_2$	1210
Carbon Dioxide	CO_2	—	44	—	—
Sulphur	S_2	32	64	(to SO_2) $S+O_2=SO_2$ (to SO_3) $2S+3O_2=2SO_3$	470
Sulphur Dioxide	SO_2	—	64	—	—
Hydrogen	H_2	1	2	$2H_2+O_2=2H_2O$	1130
Hydrogen Sulphide	H_2S	—	34	$2H_2S+3O_2=2H_2O+2SO_2$	—
Oxygen	O_2	16	32	—	—
Nitrogen	N_2	14	28	—	—
Methane	CH_4	—	16	$CH_4+2O_2=CO_2+2H_2O$	1202
Acetylene	C_2H_2	—	26	$2\ C_2H+5O_2=4CO_2+2H_2O$	900
Ethylene	C_2H_4	—	28	$C_2H_4+3O_2=2CO_2+2H_2O$	1022
Ethane	C_2H_6	—	30	$2C_2H_6+7O_2=4CO_2+6H_2O$	1000
Water Vapor	H_2O	—	18	—	—
Air	—	—	29	—	—

A real measure of the efficiency of combustion is found in the relations existing between the amount of air theoretically required for the burning of fuel and the amount of air actually supplied for such combustion. Table 3 shows the theoretical requirements for various fuels and the resulting maximum per cent. of CO_2 in flue gas for complete combustion.

Combustion Losses

In order to utilize all the heat of combustion a boiler would have to be free from radiation and leakage losses, the coal completely oxidized, and the products of combustion discharged at atmospheric temperature. Commercially such conditions are unobtainable.

A boiler which is operated constantly at eighty per cent. overall efficiency is very exceptional; seventy-five to seventy-eight per cent. efficiency is extremely good practice. The various losses which occur in combustion, including the heat utilized by the boiler, constitute the "Heat Balance." The losses considered are:

1. Loss due to moisture in the fuel.
2. Loss due to hydrogen in the fuel
3. Loss due to moisture in the air.
4. Loss of fuel through the grate.
5. Loss due to incomplete combustion.
6. Loss through the dry chimney gases.
7. Loss due to unburned fuel carried beyond combustion chamber.
8. Radiation and unaccounted for losses.

These will be considered separately.

Moisture in the Fuel

Moisture in the fuel represents a very definite loss. It must be brought from atmospheric temperature to boiling point of 212 degrees, and again raised from 212 degrees to the temperature of the exit gases. At times firemen turn the hose on the coal pile. This is of value only to assist coking or reduce dust. The theoretical furnace temperature is decreased.

Wet coal will only give a higher evaporation by preventing loss through the grate, or reducing the percentage of excess air in thin fires, as a result of packing the coal better. Don't let your firemen run wild with the hose. Watch your step in purchasing coal to see that the moisture content is specified and that deliveries conform to the contract, or else that proper adjustment is secured for excessive percentages of moisture.

Loss Due to Hydrogen

The combustion of a pound of hydrogen results in the production of nine pounds of water vapor. This moisture must be heated and discharged at stack temperature.

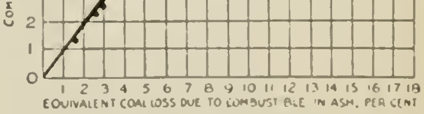

Figure 1.

---

*Specially written for Power House. Copyrighted 1923, by Robert June.

Further, since water is the direct product of combustion, the latent heat must be taken into consideration. Therefore, despite the fact that the combustion of a pound of hydrogen, liberates 62,000 B.t.u., we find that the presence of hydrogen in anthracite coal causes an approximate loss of 2.5 per cent. total heat value and with bituminous an average loss of 4.5 per cent. of the total heat value of the fuel. This loss then can be minimized only where it is practical to substitute a low hydrogen fuel for a high hydrogen fuel, without additional cost or without affecting other factors.

Loss Due to Moisture

This is usually a minor loss, but on hot, humid days, or in regions where the air is constantly sur-charged with water vapor it becomes appreciable. Since the moisture content of the air must be accepted as found the only manner in which this loss may be kept in a minimum is by the reduction of the exit gas temperature to the lowest practicable figure.

From 15 to 50 or 60 per cent. of the total weight of refuse in the ash pit is combustible matter. The quantity of this unconsumed carbon in the ash in any given plant depends upon the size and quality of the coal, the type of grate, the rating at which the boiler is operated, and to some extent upon the skill of the fireman.

TABLE II

HEAT OF COMBUSTION

By Calorimetric Determination.

Combustible	B.t.u. per lb.	B.t.u. per Cubic Foot
Hydrogen	62000	348
Carbon (to CO)	4380	——
Carbon (to CO_2)	14540	——
Carbon Monoxide	4380	342
Carbon in CO	10160	——
Methane	23850	1073
Acetylene	21460	1590
Ethylene	21450	1675
Ethane	22230	1883
Sulphur (to SO_2)	4050	——
Sulphur (to SO_3)	5940	——

In hand fired plants the total loss resulting from this waste of fuel has been found to range from 3 to 12 per cent. or more of the total heat value of the fuel. Good stoker practice should show losses ranging from one per cent. to a maximum of five per cent. of the heat value of the fuel.

The only way to find out where your plant stands on this important point, is to have a series of analyses made of representative samples of ash. If you are not equipped to make such a test yourself you can send your samples to testing laboratories in any of the large cities, which will do this work for a nominal fee.

If you find that your losses are high, study the proportioning of the grate openings to the size of coal burned; note further how your firemen handle the fire. You may find that your trouble is due to the use of coking coals, and that if it is practical to do so you will greatly reduce your losses by the substitution of free burning coals.

Incomplete Combustion

The difference between the burning of a pound of carbon to CO and burning it to CO_2 is 10,160 B.t.u. A very small percentage of CO in the flue gas is therefore fatal to high boiler efficiency. The extent of losses resulting from the presence of CO in the flue gas is shown graphically in Figure 2.

Carbon monoxide being a colorless gas, its presence in the chimney gases cannot be detected by the absence of smoke. A clear stack does not indicate perfect combustion. If you find that you are running high percentages of CO look first to the method of handling the fire on the part of the firemen. Then check up your furnace design. Remember that if ample combustion space is not provided the volatile gases will be brought in contact with the boiler surface before combustion is complete, and the CO being thus reduced in temperature, may fail to unite with the oxygen to form CO_2.

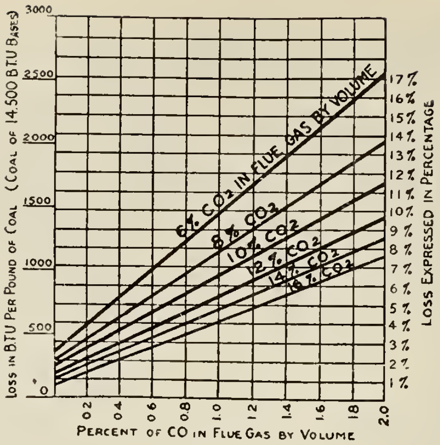

Figure 2.

Dry Chimney Gases

This is usually the greatest of all the losses. In even the best practice this loss is usually not far from 12 per cent. with a general average of from 20 to 25 per cent. The size of the loss arises in the fact that stack temperatures less than 450 degrees are seldom found except in connection with economizers, and that temperatures of 600 to 700 degrees are by far more common. Figure 3 shows the amount of heat carried away under varying conditions.

The quickest way to reduce this loss is by the installation and regular use of soot blowers. Put in soot blowers and you will find your stack temperatures greatly reduced with a consequent direct saving in fuel of from 3 to 5 per cent.

Next cut down the amount of excess air admitted to the furnace to a minimum. Eliminate air infiltration by providing absolutely tight boiler settings. And finally, keep the boilers free from scale so that they will readily absorb heat.

Unburned Fuel

When large quantities of unconsumed particles of carbon are deposited beyond the bridgewall, the fault is usually due to improper furnace design or to improper draft conditions. The fuel should be burned before it leaves the combustion chamber. If it is not, the situation demands a special study of plant conditions.

Unaccounted for Losses

These losses which it is practically impossible to measure, include; 1. Radiation loss, which varies with the size of the furnace and boiler condition of the setting. Careful tests on properly designed boiler furnaces show that the radiation loss in the very best practice does not exceed 2 per cent. 2. Losses due to unburned volatile hydro-carbons. 3. Loss due to the combination of carbon and moisture, with the consequent formation of hydrogen ($C+H_2O$ equals $CO+H_2$), which may or may not be burned. This action may occur when wet fuel is thrown on an incandescent fuel bed.

The test figures of 2 per cent. radiation and unaccounted for losses can be approximated in the average boiler plant. Unfortunately these losses are usually sadly neglected. They are frequently found to amount to as much as 10 or 15 per cent. due primarily to leaky boiler settings, as well as cinders blown out of the stack under a high draft pressure. With improperly insulated boiler settings there is just one thing to do —build the walls thicker and insulate them properly.

Smoke

Smoke consists of the gaseous and solid products of combustion both visible and invisible, including substances carried in the atmosphere with the products of combustion.

The direct loss due to visible smoke is very small. Compilation of the results of a large number of tests show that this loss as represented by unconsumed carbon seldom exceeds one per cent. It is the invisible and practically colorless gases issuing from the stack which may represent combustion losses many times greater than that due to the actual carbon in the gases. A small amount of carbon will color an immense volume of gases.

TABLE III

THEORETICAL AIR REQUIREMENTS FOR VARIOUS FUELS AND THE RESULTING MAXIMUM PER CENT CO_2 IN THE FLUE GAS FOR COMPLETE COMBUSTION.

Fuel, Moisture and Ash Free	Ultimate Analysis C.	H.	N.	O.	S.	Air, Pounds Per lb. of Fuel	Per 10,000 B.T.U.	CO_2 % By Volume
Anthracite	94.39	1.77	0.71	2.13	1.00	11.39	7.4	20.06
Semi-anthracite	89.64	3.97	0.63	3.23	2.53	11.59	7.5	20.00
Super-bituminous	86.39	4.84	1.46	5.50	1.81	11.41	7.6	18.65
Bituminous	79.71	5.52	1.52	9.87	3.38	10.70	7.4	18.46
Sub-bituminous	78.06	5.70	1.35	13.10	1.79	10.24	7.3	81.56
Lignite	70.64	4.61	1.22	22.67	0.86	8.75	7.3	19.68

TABLE IV

Heat absorbed and losses itemized	Highest attainable Efficiency	Excell'nt practice	Good practice	Average practice	Poor practice
Heat absorbed by boiler	89.86	80.0	75.0	65.0	60.0
Loss due to free moisture in coal	0.50	0.5	0.6	0.6	0.7
Loss due to hydrogen in coal evaporation of H_2O	4.20	4.20	4.30	4.3	4.4
Loss due to heat in dry flue gases	5.33	10.0	13.0	17.5	20.0
Loss due to carbon monoxide	0.00	0.2	0.3	0.5	1.0
Loss due to combustible in ash and refuse	0.00	1.5	2.4	4.5	5.5
Loss due to heating moisture in air	0.11	0.2	0.2	0.3	0.4
Loss due to unconsumed hydrogen, hydrocarbon, radiation, and unaccounted for	0.00	3.4	4.2	7.3	8.0
Calorific value of coal	100%	100%	100%	100%	100%

As a matter of fact a smoky chimney may indicate a much more efficient furnace than one which is smokeless, due to the fact that a furnace operating with a minimum air supply may cause dense clouds of smoke, and still give a higher evaporation than one made smokeless by a large percentage of excess air.

The loss due to unconsumed or partially consumed volatile hydro-carbons though not evident from the color of the gases issuing from the stack, may represent a very appreciable percentage of the total fuel fired. The way to determine this loss and to minimize it is by constant analysis of flue gas and by the application of remedies suggested by the results of such analysis.

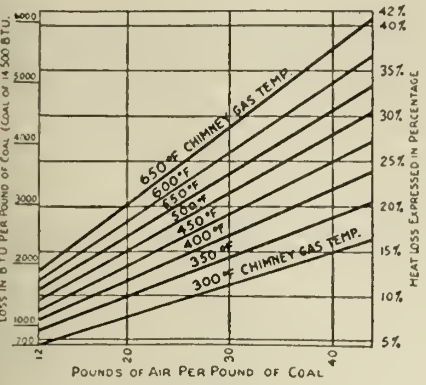

Figure 3.

Stand-by Losses

Stand-by losses include: (a) heat lost in shutting down boiler; (b) coal required to start up cold boilers; (c) fuel required in banking fires; (d) heat lost in "blowing off" and cleaning boilers. Depending upon the size and character of the boiler equipment and the conditions of operation stand-by losses will range on the average from 5 to 15 per cent. or more of the total heat generated over the period of a year. This means that if your boiler normally operates at an efficiency of 70 per cent. for example, that its actual efficiency over a period of a year will probably not exceed 60 per cent.

Bearing this fact in mind, efficient power plant managment demands that the closest watch be kept on the detail of taking off or putting boilers on the line. It is better to work three boilers continuously at a high rating if this can be done, than to work four intermittently.

Heat Balance

The heat balance consists of a chart on which a summary is made of the various losses together with the amount of heat absorbed by the boiler. It is a bookkeeper's device, very valuable to the power plant operator, for it shows him at a glance where his losses are and thus in itself suggests means for minimizing them.

A representative heat balance is shown in Table 4. To the operating man this table is of value for purposes of relative comparison only. The actual heat balance for any given plant must be worked out on the ground, with reference to the grade of fuel, type of furnace and grate, rating at which the boiler is driven, and similar factors.

Improving the efficiency of a boiler plant is a man size job. It requires enthusiasm, patience and persistence, but given these the reward is certain.

Acid in oil will cause corrosion when in contact with moisture. The presence of sulphuric acid may be determined by a solution of barium chloride in distilled water, a few drops of which put into the oil after it has been thinned with an equal amount of gasoline or benzine will cause a whitish precipitate if acid is present. In the absence of moisture the acid is not so active and may escape notice.

C.A.S.E. Notes

The regular meeting of the Canadian Association of Stationary Engineers, London of No. 30, was held in Foresters Hall on August 17, 1923, and was well attended. Past grand president George E. Moll presided. George J. Soucy, grand secretary of the Association was present, and spoke on the "good of the order," touching on the subject of what the C. A. S. E. held out to prospective candidates for membership. He also outlined the enthusiastic membership campaign being launched by the grand president, James J. Sullivan, of Ottawa.

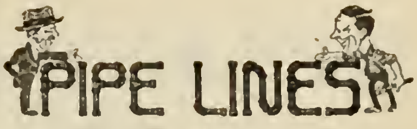
R. E. Lyons, representing the Garlock Packing Co., made a short address outlining ways and means that the C. A. S. E. could be of service to the engineers of the community. D. F. Campbell who has been conducting technical classes in steam engineering was present and consented to act on the general educational committee of the C. A. S. E.

The Grand Lodge is quite convinced that with a Minister of Labor such as Dr. Forbes Godfrey, a satisfactory advance will be made in the way of better enforcement of the act and its impartial application. A resolution of the Grand Lodge requesting the appointment of Inspectors, not members of the examining board, has been presented to the Minister of Labor, and he has promised that it will have his careful consideration.

Final plans for the annual picnic held August 18, were made. London expects to see a big increase in membership under the leadership of George E. Moll—Joseph H. Ward, Secy-Treas.

G. F. Galloway, past president of the C. A. S. E. has purchased a controlling interest in a motor business in Galt, Ont., and with Mrs. Galloway and family has moved to Galt from London.

George J. Soucy, grand secretary of the C. A. S. E., was in London, Ont., on August 18, for the purpose of presenting G. F. Galloway, with a past president's jewel. While in London, Mr. Soucy attended the annual picnic of the London No. 30, C. A. S. E. at Spring Bank Park.



UNCOVERED IN ANY OLD SPOT

The straight repulsion-type of single-phase motors may be reversed by shifting the position of the brushes from one side of the axis of the field poles to the other. The correct running position of the brushes is generally about 12 to 15 electrical deg. to the right or left of the field-pole axis.

* * *

Technical School Director: (*to engineering class*) "*What is a drydock?*"

Oshawa Student: "*A doctor who won't issue any prescriptions.*"

* * *

Singing or Hissing of Brushes: Apply a small quantity of good machine oil or vaseline with a piece of canvas and then wipe off. Just a faint trace of oil should be all that is required.

* * *

As the great steel magnate was raking Johnny, the office boy, over the coals, the lad sobbed:—"Gee, I just wish you'd put as much trust in me as mother does in a safety pin."

* * *

Bearings Out of Line: Loosen bearings by partly unscrewing bolts that hold them in place; usually they will align themselves after machine has been started and then the bolts can be gradually tightened up. This must be done with the belt off.

* * *

There is nothing suicidal about a girl hanging on a man's neck at the Canadian National Exhibition.

* * *

Overhead-sheave bearing boxes should always be packed with compression-cup grease. The grease must be pushed against the shaft once or twice a week, as sufficient heat is not generated in the bearings to cause the grease to run as in the case of continuously operated machinery.

* * *

No, Nita, it does not always indicate a cold, just because one is continually coughing up.

* * *

A synchronous motor is an alternating-current generator operating as a motor. If two alternators are connected in parallel and the prime mover of one shut down, this alternator will continue to rotate in the same direction and will pull its engine; the alternator then becomes a synchronous motor.

* * *

Teacher: "*Johnny, use the word Egypt in a sentence.*"

Johnny: "*I asked him for my change but E gypt me.*"

* * *

Coefficient of friction means the proportion of the pounds pull (or push) to the pounds (weight) being moved over a given horizontal surface; that is, wood on wood without lubricant may have a coefficient of 0.5, or require ½-lb. pull to move one pound along slowly. Or, coefficient of friction is the ratio of the force required to slide a body along a horizontal plane surface to the weight of the body.

The Value of the Slide Rule in a Power House

By **ARTHUR MURPHY**

The Solution of Simple and Everyday Problems of the Engineer With a List of Ratios Found Handy Around Power Plants

IN THE July 5 issue of Power House an outline was given of the use of the slide rule and its application to some simple calculations. This article is intended to show its applicability to some simple and everyday problems of the power plant engineer.

The placing of the decimal point, when using the rule, should present no serious difficulty, if the engineer, instead of trying to keep track of the point, will ignore it until the calculation is completed, then place it by simple arithmetic.

Example:—Multiply 2 × 30.

If on the slide rule we set the left index of C over 2 on the D scale, then under 3 on the C scale, we find 6—not 60.

Placing Decimal Points

Place the decimal point by inspection. From arithmetic we remember that when multiplying decimals we first multiply as if there were no decimal points, then count off as many decimal places as there are in the numbers being multiplied.

Problems:—

1 20 × 3
2 2 × 300
3 .2 × 3
4 .2 × .03
5 .02 × .003

In problem 4 there are three decimal places. The answer must be .006. In problem 5 there are 5 decimal places, giving the answer .00006.

The multiplication of three or more numbers presents no more difficulties than the multiplication of two, it is simply continuation.

To find the value of 4.1 × 56 ×.26 × 49.

Using scales C and D, set the right index on C to 41 on D and then move the indicator to 56 on C. We have now multiplied 41 × 56. The result so far is 2,296 opposite the indicator on scale D, neglecting the decimal point.

Now set the left index of C to the indicator and move the indicator to 26 on C. On D under the indicator is 597.

Set the right index to the indicator and move the indicator to 49 on C, on D. Opposite the indicator find 2,925, the answer. The position of the decimal point is fixed by inspection. 4.1 × 56 × .26 ×.49 is roughly 4 × 60 × ¼ × ½ or 30. The answer then is 29.25.

It is not necessary to read the result of each step in the calculation as has been done above, read nothing but the final result. In this way, provided care is taken in the setting of the indicator and the slide, the only place for inaccuracy in reading the graduations is in the answer. The slide rule can be relied upon to give fairly close figures, even in a problem involving several settings of the slide and the indicator.

Cube Roots

Occasionally the engineer will have to find the cube root or the cube of a number. The K scale is used for this operation in conjunction with the D scale. To find the cube of a number, set the indicator to the number on the D scale and read the cube on the K scale.

Finding the cube root requires more caution, the scale is divided into three parts. Suppose we wish to find the cube root of 270. As a rough guess it is a little more than 6, thus we would set it to somewhere between 6 and 7 on the D scale and then look on the K scale and find the division in which the 27 occurs and set the indicator to the correct place. Read the answer 6.46 on the D scale.

Area of Circle

To find the circumference of a circle having a diameter of 16 inches.

The circumference of a circle is 3.1416 × the diameter, usually written π × D.

Set the left index of the C scale over π on the D scale. Under 16 on the C scale read the answer 502 on the D scale, and since 3 × 16 is about 48, the answer must be 50.2.

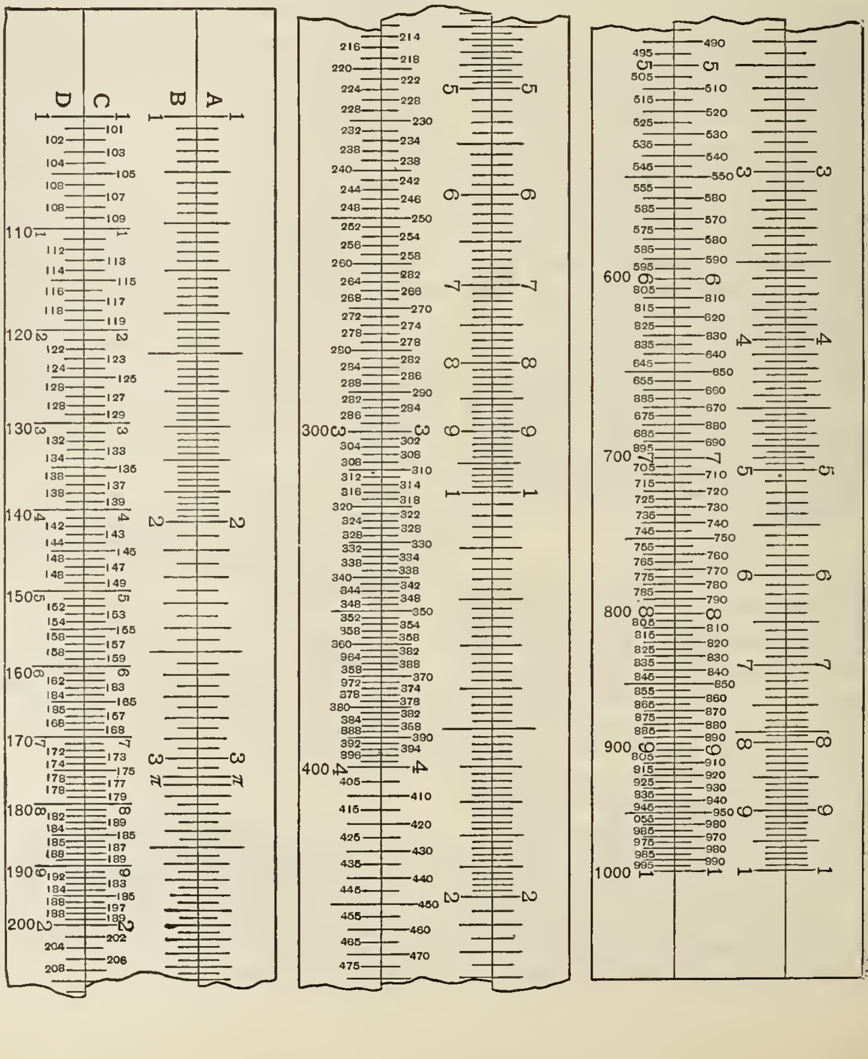
To find the area of a circle whose diameter is 8 inches.

The general formula for the area of a circle is πr^2 where π is a constant = 3.1416 and "r" is the radius of the circle.

On the slide rule π will be found on the D scale. Multiply 4 × 4, using scales C and D, then multiply by π.

Set the right index on scale C over 4, the radius, on scale D. Set the indicator to 4 on scale C, then move the slide till the left index of scale C is under the line of the indicator. Under π on scale C read 5.02 on scale D.

Another handy formula for the area of a circle is .7854 × D^2. This is convenient for the slide rule as it is then



ot necessary to divide the diameter by to get the radius.

To find the area of the 8-inch circle y this rule.

Set the right index of the C scale over 7854 on the D Scale. Under 8 on the scale set the indicator, then move the ide till the right index is in line with he line on the indicator. Under 8 on the scale read the answer 5.02 on the D cale.

Find Horse Power

Find the horse power of an engine unning 250 r.p.m., with a weight of 100 ounds on the scales, the length of the rake arm being 4 feet.

The formula for H. P. is $\frac{2 \pi r n w}{33.000}$.

where

r = length of brake arm, in the case of a rope brake, "r" is the radius of the pulley.

n = revolutions per minute.

w = net weight or effective weight on the scale.

The H. P. of the engine is

$$\frac{2 \times \pi \times 4 \times 250 \times 110}{33,000}$$

Using scales C and D multiply 11 by 25, divide by 33, then multiply by 8, then by π, and by inspection the 190 we found by the slide rule must be 19.0.

Useful Ratios

The slide rule will be found to be of value to the engineer in problems involving proportion as when finding the lb. per sq. in., equivalent to head in feet, United States gallons to Imperial gallons, etc.

As an example, suppose we wish to find the number of Imperial gallons corresponding to 1,200 U. S. gallons.

$$\frac{6 = \text{U. S. gallons}}{5 = \text{Imperial gallons}}$$

Thus the number of Imperial gallons

$$\frac{5 \times 1800}{6} = 1500$$

On the slide rule this is an easy calculation, and its use will shorten the time required to change a table given in U. S. gallons to the Imperial gallons. so that it can be used in Canada.

Place the 6 on the C scale over the 5 on the D scale, then under 18 on the C scale, read the answer 15 on the D scale.

As another example find the number of pounds per sq. in. equivalent to a head of 34 feet of water.

In the manuals published by the slide rule makers the usual method of indicating a problem of this nature is

C	Set 60	Under 34
D	To 26	Find 14.75 pounds = answer

Or, in other words, on scale C set 6 over 26 on the D Scale, then under 34 on the C scale find 14.75 on the D scale.

The following list of ratios will be found handy around the power house for quick calculations, the departure in no case from the exact ratio exceeding one in a thousand.

$$\frac{\text{Set } 226 = \text{Diameters of circles}}{\text{To } 710 = \text{Circumferences of circles}}$$

$$\frac{70 = \text{Side of square}}{99 = \text{Diagonal of square}}$$

$$\frac{6 = \text{U. S. gallons}}{5 = \text{Imperial gallons}}$$

$$\frac{430 = \text{Imperial gallons}}{69 = \text{Cubic feet}}$$

$$\frac{26 = \text{Inches}}{66 = \text{Centimeters}}$$

$$\frac{82 = \text{Feet}}{25 = \text{Meters}}$$

$$\frac{46 = \text{Imperial gallons}}{209 = \text{Liters}}$$

$$\frac{57 = \text{Inches of mercury}}{28 = \text{Pounds per square inch}}$$

$$\frac{60 = \text{Feet of water}}{26 = \text{Pounds per square inch}}$$

On Trip West for Power House

Walter J. Hudson to Give Unique Service to All Engineers "Stumped" by Problems

WALTER J. HUDSON.

THERE are perhaps few men in engineering circles in Canada who would hold the same interest among stationary engineers and power plant operators as Walter John Hudson, who now lives in Toronto. Mr. Hudson has had an enviable experience in all work in connection with the operation of steam power plants. Born at Burton-on-Trent, Staffordshire, England, on June 17, 1860, attended the public schools until he was 13 years old, and became an apprentice in the machine shop of the Cannock-Rugley Coal Co., transferring himself three years later to the engine room.

By diligent application, Mr. Hudson qualified as a stationary engineer in 1881, coming to America to fill a position in this capacity with the Oliver Iron & Steel Co., Pittsburg, Pa., which he held for three years. Seeking further advancement, he became employed with Chess Cooke & Co., and the Republic Iron Works, finally being appointed chief engineer of the Pittsburg Incline Co., and superintendent of the Monongahela Incline Planes Co.

For nearly seven years he was master mechanic of the Western Penitentiary, Pittsburg, Pa.

Coming to Canada in 1913, he was appointed engineer at the plant of the Moffatt Stove Co., at Weston, Ont., later becoming chief engineer at the C. P. R. and Dominion Express Company's building at Simcoe and King street, Toronto, a position he held for four years before being appointed chief engineer at the Standard Sanitary Manufacturing Company's plant, Royce Avenue, Toronto, and later superintendent of production of the Coca-Cola Co., Toronto.

Mr. Hudson is a prominent member of the F. & A. M., being past master of his lodge, and a member of the I. O. O. F., and past district deputy master of No. 3 district, Pittsburgh. He is a past chief of the Universal Craftsmen Council of Engineers, and resigned his position as secretary of Toronto No. 27, on August 27, 1923.

He is now making a service trip to Winnipeg, and on his return will call at Kenora, Port Arthur, Fort William Sudbury, Sault Ste. Marie, and other cities, in the interests of Power House. He is at the service of all engineers and operators, and his varied experience in all work pertaining to steam efficiency should be of great value in solving perplexing problems in the power plant.

The town of Unity, Sask., has purchased one 90 h.p. Vickers-Petter, semi-Diesel, heavy oil engine.

Two 550 h.p. Vickers Diesel engines, direct connected to Westinghouse generators, were recently installed in the Hollinger Gold Mines.

Tenders have been called for by the City Clerk, City Hall, Vancouver, B. C., for a hot-water heating system in the Relief Building, 530 Cambie Street, Vancouver.

Modern Practice in the Transmission of Power

The Transmission Gear Must be Taken Into Consideration in Order to Eliminate the Absorption of More Power Than is Actually Required by the Machines

THE importance of ascertaining accurately the loss of power in power transmission gear is now becoming recognized. It is impossible to estimate the efficiency of any power system unless the transmission gear is taken into consideration, for this may be absorbing more power than is actually required by the machines in the plant.

For a number of years the question of the individual electric drive has been coming more and more into prominence, for instances are constantly occurring where appreciable sums have been saved by the elimination of mechanical transmission gear.

It is a mistake to imagine, however, that the individual drive is always the most economical, for this is not the case. Its efficiency depends largely on two factors: (a) The h.p. required by the machine; (b) the percentage of working hours that the machine actually requires power from the motor.

If Horse Power is Large

Should the h.p. of the machine be fairly large, and the number of working hours per week small, the individual electric drive should always save power, provided the machine was previously driven from a line of shafting that was constantly in use.

In some cases the individual electric drive may even effect economies when the line shafting was not constantly in use, owing to the power loss in the shafting when the machine in question was receiving power.

In the majority of workshops the machines individually require little power, so that the savings that may be made by the individual drive may be so small as not to warrant the additional expenditure. The whole question depends on the efficiency of the mechanical transmission gear.

Before considering this question any further it would perhaps be as well to deal with the efficiency and layout of mechanical transmission gear. Although the value of chain driving is becoming more generally recognized, belt driving is still the most favored system of transmitting power.

Lower Expenditure

This is largely due to the lower expenditure involved and the simplicity of this method.

Every engineer knows the troubles attendant on the use of tight belting, and the difficulty often experienced in avoiding this. Tight belting is a constant source of trouble and expense, and may cause damage to the journals and shafting.

Although belt slip is usually considered to exist only to a small extent, it is a fact that a belt slip of from 5 to 10 per cent. is the rule rather than the exception. Belt slip is the cause of a great deal of trouble, and besides damaging the belting often ruins both wood and metal pulleys, owing to the heat that is generated by the slipping. Wood pulleys have been known to catch fire and metal pulleys to expand and crack under these conditions. The decreased production must also be taken into consideration, as time, output and labor are wasted owing to the slower working speed of the machinery.

Primary Points

The primary points to be considered when designing a belt drive are as follows:

(1) Ratio of the diameter of the driving to the driven pulley.

(2) Distance between shaft centres.

(3) Speed of the shafting in revolutions per minute.

(4) Belt speed in feet per minute.

(5) Arc of contact on the smaller pulley.

(6) Co-efficient of friction between belt and pulleys.

(7) Belt slip and creep.

(8) Jointing of the belting.

(9) Size and type of belting.

There are also a number of smaller considerations dependent on the above conditions. For practical purposes, unless a drive is to be mathematically worked out in every respect, the co-efficient of friction is not always taken into account, although if really reliable figures are required this should be done. Variation of any one of the above conditions affects one or more of the other conditions, so that considerable care must be taken when planning an efficient drive, particularly if expense is an important condition, as is usually the case.

The greatest difficulty when planning a drive is usually to reconcile the ratio of the diameters of the driving and driven pulleys with the available distance between the shaft centres. There are many rules in use for this problem, one of the most practical giving a distance between the shaft centres of 18 times the diameter of the smaller pulley.

A Minimum Distance

For example, with a 6-in. pulley driving on to a 30-in. pulley this would mean a minimum distance between shaft centres of 9 ft.

Some authorities go much further than this and specify a fixed minimum distance between shaft centres under any conditions. The following table shows the minimum distances between shaft centres adopted by one of the best authorities:—

Ratio of Driver to Follower	Minimum distance between Shaft C'ntres	Ratio of Driver to Follower	Minimum distance between Shaft C'ntres
1 to 2	8 feet	1 to 4	12 feet
1 to 2.5	9 feet	1 to 4.5	13 ft. 6 in.
1 to 3	10 feet	1 to 5	15 feet
1 to 3.5	11 feet	1 to 6	18 feet

Drives planned in accordance with this table will give very high efficiencies, and it is wise whenever possible to keep to these figures. Certainly a shorter distance than 18 times the diameter of the smaller pulley should never be employed if at all possible.

Electric motors are now used in every kind of workshop, and owing to the comparatively high speed at which most of them work, drives with high-speed ratios are largely in use. Electric motors of a given h.p. are much cheaper when made for a high speed and the temptation is therefore to invest in a high-speed motor and arrange the transmission gear accordingly.

Choice of Motor

Unfortunately the choice of the motor is not always left to the engineer who is

LINE SHAFTING

Diameter of Shaft in inches ...	1½	1¾	2	2¼	2½	2¾	3	3¼	3½	4	½	5
R P M	Maximum Distance between bearing centres in feet											
100	7½	7¾	8¼	8¾	9¼	9¾	10¼	10¾	11¼	11¾	12¼	13¼
150	7	7½	8	8½	9	9½	10	10½	11	11½	12	13
200	6¾	7¼	7¾	8¼	8¾	9¼	9¾	10¼	10¾	11¼	11¾	12½
250	6¼	7	7½	8	8½	9	9½	10	10¼	10¾	11¼	12
300	6	6¾	7¼	7¾	8¼	8¾	9	9½	9¾	10¼	10¾	11½
350	5½	6¼	7	7½	8	8¼	8¾	9	9¼	9¾	10	11¼
400	5¼	6	6¾	7¼	7¾	8	8¼	8½	8¾	9	9¼	9¾
500	4¾	5¾	6½	6¾	7¼	7¾	8	8¼	8½	8¾	9	9½
600	4½	5½	6¼	6½	6¾	7¼	7½	7¼	8¼	8½	8¾	0¼
700	4¼	5	5¾	6	6¼	6¾	7¼	7½	8	8¼	8½	8¾
800	4	4½	5¼	5½	5¾	6¼	6¾	7¼	7¾	8	8¼	8½
1000	3¾	4¼	4¾	5	5¼	5¾	6¼	6¾	7¼	—	—	—

usually called in to fix the motor and fit up suitable transmission gear.

This is a pity, for it is often necessary to use two or three countershafts in order to get the required speed ratio, and this means waste of power and additional expenditure. On the other hand, if the motor is some distance from the machines, a high speed may be advantageous, as smaller shafting and belting may be used for the countershaft drives.

The h.p. that shafting of any given size will carry varies directly with its speed. On the other hand, the maximum distances between the journals decrease as the speed of the shafting increases, although not in direct proportion. The following formulae are for the h.p. which mild steel shafts of good quality will transmit at various speeds:—

No. 1. Head Shafts: $\dfrac{(\text{dia. of shaft})^3 \times \text{r.p.m.}}{100}$

No. 2. Line Shafts: $\dfrac{(\text{dia. of shaft})^3 \times \text{r.p.m.}}{66\ 2/3}$

No. 3. Transmission Shafts: $\dfrac{(\text{dia. of shaft})^3 \times \text{r.p.m.}}{50}$

If these formulae are adopted the maximum distance between adjacent bearings supporting the shafting will be found in the tables accompanying this article.

Subject to Explosions

Where the shafting, however, receives its power from gas or oil engines, and is therefore subject to shocks from the explosions of the engine, stronger shafting should be used, a given shafting being capable of carrying safely approximately 30 per cent. less power under these conditions.

One of the most important features of power transmission gear is the bearings. Upon their suitability for the work depends to a certain extent the success of an installation. It is commonly believed that the metal of the bearing rubs against the shafting, and that the friction of a bearing depends upon the materials of which it is composed. This is not the case should the bearing be properly lubricated. The lubricating oil or grease imposes a thin film between the two metals and prevents actual contact, so that it is immaterial what metal is used, if properly lubricated, as far as friction is concerned.

Excessive pressures may squeeze the oil out of the bearings, and the metals then come into contact, in which event the heat generated will cause them to expand and grip each other, causing a "seize."

Tight Belting Dangers

Tight belting is particularly responsible for this evil, the continual heavy drag on the bearing tending to break the oil film far more easily than heavier intermittent loads.

Both belt slip and tight belting are caused through the belt getting insufficient grip of the circumference of the smaller pulley, this in turn being due to too high a speed ratio for the distance between shaft centres.

Where conditions permit of no improvement, the difficulty to a certain extent may be overcome by the use of a wider belt.

It has been conclusively proved that the friction between belt and pulley varies considerably with the speed, so that for correct calculations the co-efficient of friction must be taken into consideration. In ordinary practice this varies between .3 and .5 for leather belting running on cast-iron pulleys. The following table gives the co-efficient of friction at various belt speeds:—

Speed in ft. per minute	Co-effic'nt of friction	Speed in ft. per minute	Co-effic'nt of friction
600	.298	3,500	.437
1,000	.327	4,000	.453
1,500	.355	4,500	.468
2,000	.379	5,000	.483
2,500	.400	5,500	.497
3,000	.419	6,000	.510

Greater belt slip is liable to take place at high-belt speeds, owing to the action of centrifugal force.

Belts should not work at a speed exceeding 5,250 ft. per minute, owing to centrifugal force, and also because this is the safe limit of periphery speed for cast iron pulleys of ordinary construction.

Generally speaking, from 1,000 to 2,000 ft. per minute for machine drives, and from 3,000 to 3,600 ft. per minute for main belts conforms to good practice.

HEAD SHAFTING

Diameter of Shafts in inches	Distance between centres of Bearings in feet

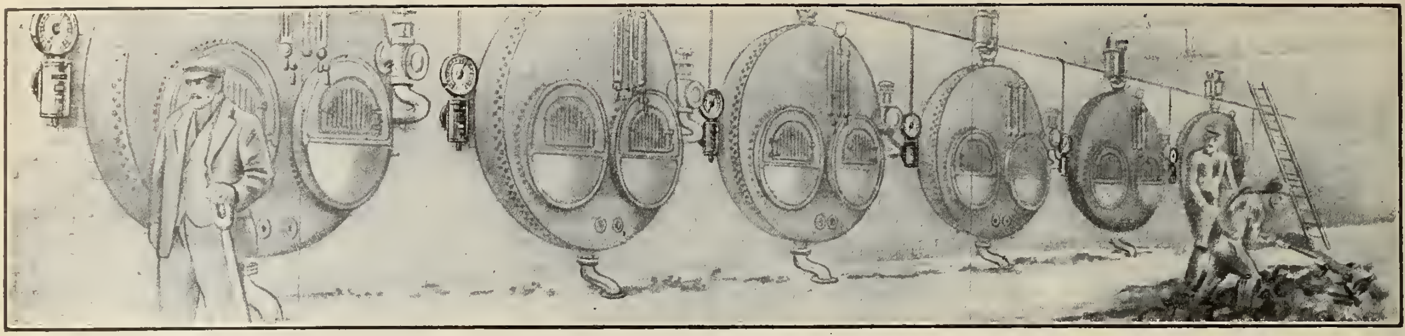
C. A. S. E. Notes

James J. Sullivan, grand president of the Canadian Association of Stationary Engineers, attended the convention of the association for the first time in 1921 as delegate from Ottawa No. 6. For two years he was president of Ottawa No. 6, being elected grand treasurer in 1922, and grand president in 1923.

JAMES J. SULLIVAN.

For the past twenty-six years, Mr. Sullivan has been plant superintendent of the Continental Paper Products, 147 Booth street, Ottawa, and is considered an expert on paper bag machinery and construction and maintenance work in paper bag factories.

Mr. Sullivan spent a year in Krappitz, Germany, supervising the reconstruction of the factory of the Continental Paper Products there. His present address is 20 Jeanne D'Arc St., Hull, Quebec.



Easy Engineering Lessons in the Power House

By M. BARRY WATSON, B.A.Sc., M.E.
Director of Engineering, Central Technical School, Toronto.

ACCURACY, when dealing with measurements, is a purely relative term in that we are physically unable to measure absolutely accurately, and therefore any calculations we may make, using such measurements as a basis, cannot give results more nearly accurate than the original measurements.

Absolute accuracy can only be obtained in calculations based on exact data, such as a case of a man working 44 hours a week at 75c. per hour, we know his weekly pay to be exactly 44 × .75 = $33.

Accurate measurements cannot be obtained because we have not instruments which will measure absolutely accurately. In grinding a piston rod to size, a machinist will use a micrometer to measure the diameter, which is graduated in 1/1,000-inch divisions, or, perhaps, in 1/10,000 inch.

No matter how hard he may try, he cannot get the diameter closer to the required diameter than 1/20,000 of an inch with this instrument. However, when he gets the size correct within, say, 2/1,000 of an inch he will call it close enough, because he knows the packing will expand and contract sufficiently to prevent leakage with that much or more variation in size.

In this case it is seen that even the accuracy which the machinist might have obtained is quite unnecessary. Gauges have been made which are correct within one millionth of an inch, but we cannot be sure that they are absolutely accurate, for they may be several ten-millionths of an inch out, and we have no way to tell. In any case it makes no difference.

The majority of measurements taken by an engineer are seldom more accurate than 1/32 of an inch, or perhaps 1/64. Suppose an engineer ground down an old piston rod, originally 1¼ in. diameter; by means of calipers and scale he might get a measurement of 1-9/64 in. This would be plenty close enough, but it is not accurate, because if it is 1/128 in. either larger or smaller than this size he cannot measure it. In this case the possible variation from the measured size is 1/128 in. either way or a total of 1/64 in., which is 1/64 ÷ 19/16 × 100 = 1.37 per cent.

In measuring a three-foot square pump foundation, the measurements would be sufficiently accurate if correct within say ½ in. either way. This allows one inch variation in 72, or about 1/72 × 100 = 1.39 per cent. Thus a variation of one sixty-fourth of an inch in a piston rod diameter is relatively no more accurate than a variation of an inch in such a foundation, although the accuracy of measurement was much greater.

Measuring a Coal Bin

In measuring a coal bin, forty-nine feet long, the average engineer would be satisfied to call it fifty feet, which would would be within one part in fifty, or two per cent. of the correct measurement. On the other hand, in measuring the diameter of a three-foot engine cylinder, most engineers would try to measure within at least 1/32 inch, which is one part in 1,152 parts, or closer than 1/10 of 1 per cent.

Thus it is seen that different measurements require different degrees of accuracy, and the good engineer is the one who can tell which measurements should be made to any particular degree of accuracy.

Suppose we desire to know how many tons of coal a bin 48 ft. 6 in. × 10 ft. 3 in. × 9 ft. 1½ in. will hold. Assuming these dimensions as accurate, we would get for the volume of the bin 48.5 × 10.25 × 9.125 = 4536.265625 cu. ft. We must now assume the weight of a cubic foot of coal. Let us say that coal weighs 40 cubic feet to the ton, then the weight of coal in the bin would work out as

$$\frac{4536.265625}{40} = 113.406640625 \text{ tons of coal.}$$

It is easily seen that we might as well neglect all but the first two decimal places, because .0066 tons is only 13.2 lbs., and it would be easy to either add this much coal to the bin or take that much out without appreciably affecting its height; but we have done a lot of work in multiplying and dividing to get these figures which turns out to be wasted work. The coal might have weighed one ton to each or to each 41 cubic feet.

Weight May Vary

In the former case the weight of coal in the bin would be only about 110.7 and in the latter case about 116.2 tons. Thus, although we took our measurements of the bin with considerable accuracy, our result may be a long way out, because our estimate of the weight of the coal was not relatively as accurate. We shall now see that we did not need to take such accurate measurements of the bin and could have saved a lot of work.

The accuracy with which we took the relation between weight and volume of coal was one part either way, or two parts in 40, which is 5 per cent. This means that our result was only within 5 per cent. of the correct weight. Thus, if we take our measurements of the bin within 5 per cent, our final accuracy will probably be just as close. For example, let us call the bin 50 ft. × 10 ft. × 9 ft. = 4,500 cubic feet.

Our length is taken 1½ parts in 50, or 3 per cent. too great, our width is taken ⅛ part in 9 parts, or about 1.6 per cent. too small.

It will be noticed that when using approximate sizes in this way it is better to average them up by taking some too small and some too large. 4,500 cubic feet at 40 cubic feet to the ton of coal would hold 112½ tons. This is well within the limits which we found our error in the weight of coal showed us to be possible, and it is just as likely to be correct as any of the other results we got, and we have saved an enormous amount of arithmetic in working this out.

Errors in Measurement

From the above it is seen that we need not strive for absolute accuracy in every measurement, and that, in fact, we can sometimes introduce errors in measurements by using approximate values instead of measured values and still get a result which is likely to be just as accurate.

Let us take an example of finding indicated horse power of an engine, using the formula $\text{H. P.} = \frac{P \times L \times A \times N}{33,000}$. The Mean Effective Pressure, represented by P, will likely be measured by means of indicator cards, and the measurements taken off cards by different people are found to vary within several per cent., showing that the accuracy of this measurement may be considerably out. The length of the stroke is likely to be correct within a very small percentage; but the speed, if counted by means of an ordinary speed counter, is likely to be inaccurate. Therefore, if we calculate the area of our piston within one or two per cent., our result will be as nearly accurate as we can get it anyway.

Now, if we use a micrometer to measure the diameter of the piston rod, in order to subtract its area from that of the piston on the crank end, we may find it to be 1-5/16 in., which gives an area of about 1.353 sq. in.; is it worth while calculating this area any closer, or even as close as above? Let us suppose that the diameter of the cylinder is 10 inches. The area of the piston on which the steam acts will be about 78.54 sq. ins. on the head end, and 78.54 — 1.353 sq. ins. on the crank end. It is obvious that we might as well have called the area of the piston rod 1.35 sq. in. because we have not in this case calculated the area of the piston farther than the second decimal place.

Let us see what effect it would have if we use 78.5 — 1.5 instead of the above. We will get as a result 77.2 instead of 77.19, which is an error of 1 part in 7,720 parts, or $\frac{100}{7,720} = 0.013$ per cent. Obviously this is still far more accurate than the other measurements we have taken, and might have simplified it further still.

Let us call the area of the piston 1 sq. in. and see what error we get. This will leave a net area of 77.5 sq. ins. which is an error of 31 parts in 7,750 parts which gives a percentage error of $\frac{31 \times 100}{7,750} = 0.4$ per cent., or less than ½ of 1 per cent.

Even if we neglect the area of the piston rod altogether on the crank end it only makes an error of 1.35 parts in 78.54 parts which is about $\frac{1.35 \times 100}{78.54} = 1.72$ per cent. Therefore, if our measurements of speed, pressure, etc., are only correct within, say, 2 per cent., we will be just as nearly accurate in the final result if we neglect the piston rod altogether. However, if the pressures are measured by means of a large number of cards measured by several people, and the speed taken over a long period of time, the results will, of course, be much closer than the above accuracy, and it will be necessary to take the piston rod into consideration.

Judgment of Engineer

In the above problems we worked out some of the results which farther than necessary, and it is in determining how far calculations of this kind should be worked, to give sufficiently accurate results, that the good or bad judgment of an engineer is shown. In this respect, the question is asked quite frequently: "To how many decimal places should a problem be worked?"

There can be no answer given to this question, because it is similar to asking: "How closely should anything be weighed?"

You could not give a general answer, such as: "Exact within an ounce," or "correct within ten pounds," because it all depends upon what you are weighing.

If you are buying a sheet of packing by weight you would weigh it within the nearest ounce, but in weighing a truck load of coal you would consider it quite satisfactory if weighed to the nearest ten pounds.

Some people teach a rule which says: "Work a problem correct to four decimal places." We shall see that such a general rule is absurd.

Let us suppose we measure a tank with a two-foot rule, and calculate the volume to be 1376.4268 cubic feet. Here we have an apparent accuracy in figures of one part in over thirteen million parts. An accuracy of this degree is absolutely unobtainable with a two-foot rule, in fact it is probable that the rule itself is much more inaccurate than that. We have, however, worked the above to four decimal places. The above tank might be said to be a 1376½ cubic feet tank, but more likely it would be said to contain 1,375 cubic feet, and the latter is just as likely to be correct as the former, considering the way in which the measurements were taken.

Thus, in this case, four decimal places are seen to be at least four too many. On the other hand, suppose we calculate the cost of pumping water to be $0.0008487 per gallon. If we only work this correct to four decimal places we would get $0.0008 per gallon.

Now, if we want to find the cost of pumping a million gallons of water, its actual cost would be $848.70, while, if we had used only the four decimal places, as above, its cost would work out to be $800.00, an error of $48.70, which, as we all know, is too big an error to be neglected. In this case four decimal places were far too few. Thus it depends entirely on conditions as to how many decimal places should be used.

Significant Figures

Instead of "How many decimal places?" the question should be: "How many significant figures?" By significant figures we mean those which signify something, and, therefore, these include all the digits except 0, which by itself signifies nothing.

In most engineering calculations, four significant figures will be found to be sufficient. In the foregoing examples we see that 1,376, or even 1,375, is quite accurate enough for all practical purposes for the volume of the tank, while for the cost of pumping water, using four significant figures, $0.0008487 still may give us an error of several cents on the cost of a million gallons, therefore it is not too accurate.

Very often three, or sometimes two, significant figures are sufficient in engineering work, and much time and work can be saved in using as few as required without sacrificing accuracy. For example, if a coal bin is 122 ft. 6 in. by 23 ft. 9 in., we might as well call it 120 ft. by 24 ft., thus using only two significant figures, but saving a great deal of calculation. The area by the measured sizes would be 122.5 × 23.75 = 2909.375 square feet. By the assumed sizes the area would work out at 120 × 24 = 2880 square feet. The error here is about 29 sq. ft. in about 2,900 sq. ft., or one part in 100, or 1 per cent., which is as close as we can measure the weight of a cubic foot of coal, therefore sufficiently accurate.

When simplifying figures for calculation in this way, it is worth while to try to keep the error as small as possible. Thus in the above case of multiplication we reduced the 122½ to 120, while we increased the 23¾ to 24, which gave us a smaller error in the product than if we had either increased or decreased both the factors. In the case of division, the error in the result is minimized by either increasing or reducing both numbers at the same time in simplifying them.

Increase in Divisor

For example, if we desire to divide 1378.3 by 19.8, we see at once that it will be much easier to divide by 20 than 19.8, which is an increase in the divisor, in order to reduce the error as far as possible we should increase the dividend also, let us make it 1380. The quotient will be 1380/20 = 69. Whereas, if we use the original numbers, the quotient will be 1378.3/19.8 = 69.61. The error in this case is 61 parts in 6900 parts or less than 1 per cent. If we had reduced the size of the dividend, say to 1378, we would have got for a quotient 1378/20 = 68.9, which is an error of 0.71 or 71 parts in 6900, which is a greater error than 1 per cent.

In making calculations in our work we must have a clear understanding of the difference between errors and mistakes. An error is an unavoidable difference, due to inaccuracies in measurement, or a difference due to unimportant facts or figures which have purposely been neglected in the calculations. While mistakes are unintentional slips in the calculations, they must be avoided by all possible means while errors may be introduced provided they make no important difference in the result.

Electricity in the Power House

By J. A. BURNETT, M.E.I.C., Consulting Engineer, 205 St. James St., Montreal.

THE induction motor may be either of the squirrel cage or the slip-ring type. The squirrel cage is for performance with easy starting conditions, the slip-ring for heavy starting conditions. The squirrel cage type costs less than the slip-ring, which requires a drum-type controller and external resistance usually of the grid type.

In addition there is the high torque type of induction motor suitable for freight elevators. The efficiency in this type is low, and it is made only in sizes up to ten h.p. This type may be thrown directly on the line, requiring no auto starter, but necessitating extra heavy wiring and fuses.

In the induction motor practically the only parts requiring attention are the bearings. These are subject to wear and in time the rotor will drop sufficiently to rub on the stator causing the motor to smoke. This requires immediate attention; if neglected, the bottom coils will be destroyed due to the heat generated by the friction of the rotor against the stator.

This condition can readily be detected by using a wooden lever and a block to raise the pulley end of the motor, a slight movement indicating a worn bearing.

Babbitt Bearings

The great majority of motors use babbitt bearings. The white metal alloys are solid materials, composed of two or more items, such as aluminum, zinc, nickel, tin, lead, copper, antimony and bismuth, in varying quantities, and fluxed and alloyed in various ways.

Originally babbitt metal had a fixed composition, being made up of 90 per cent. of tin and 10 per cent. of copper and antimony, the last to make it expand when it cools and fill the mould, but at the present time the term babbitt metal signifies no definite composition for there are babbitts made up according to fifty different formulas, on the market.

Except in a few cases, but two babbitts, one a lead-base alloy and the other a tin-base alloy, each being the best that can be made, are required for a complete line of bearings, ranging in weight from a few ounces to several tons.

Lead-Base Softer

Lead-base babbitt is softer than tin-base babbitt, as a general rule, and is cheaper because lead costs from one-quarter to one-fifth as much per pound as tin. It is readily appreciated that babbitt can cost anywhere from the price of lead to the price of tin, depending on the proportions used. However, the cheapest kind of bearing metal which when properly lubricated will give efficient service, is equally desirable compared with the expensive metal which gives no better service.

A successful bearing is attained only when the metals are melted slowly, thoroughly, without overheating, kept at a constant temperature while working, and poured properly at the correct temperature.

Lubrication Needs

Mineral oils are all petroleum products, and form the whole, or the greater part of most of the lubricants employed. The generally accepted qualifications of a good lubricant are: first, body (i.e. viscosity), enough to prevent the surfaces to which it is applied from coming in contact with each other; second, freedom from corrosive acid, of either mineral or animal origin; third, as fluid as possible, consistent with sufficient body; fourth, low coefficient of friction; fifth, high "flash" and burning point; and sixth, freedom from all materials liable to produce oxidation or gumming.

Ring lubrication is the preferred form for most horizontal motors. The oil reservoirs, dimensions of rings and oil grooves in the bearings must be carefully designed, as a defect in any one will materially affect the heating. A recent improvement is the substitution of a number of laminations instead of a single oil ring. This decreases the possibility of the oil ring sticking, because with a number of laminations it is not probable that all of them would stick at the same time.

Ball and roller bearings have been used in electric motors to a limited extent, and it is generally admitted that at a low speed the friction of ball and roller bearings is less than the babbitt bearing. Both ball and roller bearings must be carefully mounted, otherwise they are liable to make considerable noise.

Care at Starting

Where a motor is installed in an out-of-the-way place, and where zero weather may prevail the motor should receive some attention at the time of starting. The engineer should squirt some warm oil on the bearings or the oil rings, otherwise the motor bearings may seize due to the bearing oil not circulating properly.

A no-voltage release device is essential in all installations in which when the power has failed the resumption of the supply causing the machine to start unexpectedly, would be liable to injure anyone who might be at work around the machine.

When the power goes off it should be possible only for the operator to start the motor.

A large user of electric power should ascertain whether or not it is possible to be served with at least two or more primary circuits from the substation. Double throw switches should be installed to make a quick change in case of failure of supply.

Slip-Ring Induction Motor.

Practical Ideas From Practical Men

CARE OF PUMP VALVES

MUCH economy may be effected by paying attention to the valves of pumps. A certain plant had a number of pumps of different types and makes working on high pressure. The seats of all these pumps had been neglected for some time, and were in bad condition. In addition to these pump valves there were six angle blow-off valves on the boilers fitted with brass seats and a babbitted disc which was renewed at intervals to reduce the leakage to a minimum.

The seats eventually became badly cut, and there was no means of reseating them. After looking round for a suitable machine it was decided to make one which would answer the purpose of reseating the pump and blow-off valves and also any large globe valves about the plant.

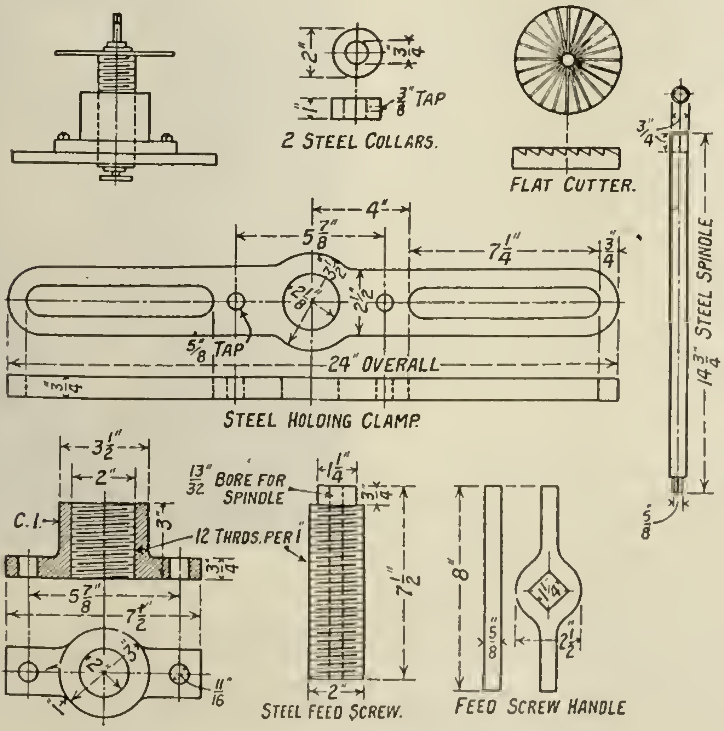
The accompanying drawing shows the arrangements, details and dimensions of the several parts with the cutter used for flat seats. Some of these pumps had seats on an angle of 45 deg., in which case a cutter of the proper shape was used. The body of the machine was made to fit the studs on the pot-valve type pumps, the bolt holes taking the valve cap studs and also the hinged studs on the blow-off valves.

The studs on the extension bar also fit these holes, and it is bolted to this when used on flat valves in the ordinary type of boiler feed pump. When reseating the discharge valves in this type of pump, which are usually level with the top of the discharge valve chamber, a block is placed under each end of the bar, and it is bolted down tight with the studs that hold the discharge chamber cap on.

In making this machine the only difficulty was to get a good cutter. If means are not at hand for making the cutter it would be best to purchase it from a company making milling machine parts. Where hard rubber valves are used they may be scraped to fit after the seats have been refaced. With brass valves, and especially those having a seat at 45 deg. angle, they should be ground in to fit with a grinding compound made up of cup grease, into which has been worked as much powdered glass as it will take without becoming too stiff. This compound will stick to the surface to be ground, and will not run off like oil.

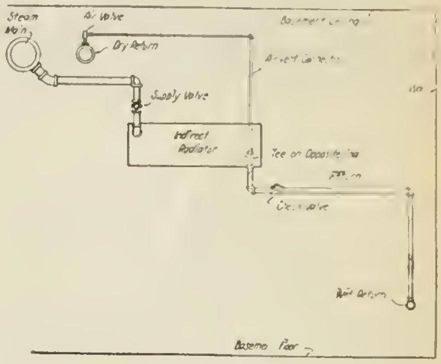
When this machine was used on the blow-off valves occasionally the steam and water issuing from the open end of the blow-off pipe were kept down to a minimum. Each valve could be reseated several times, and when the seats were worn out they were knocked out and new ones were made and put in.

In most power plants there are but few globe valves above 4 in., as gate valves are more frequently used except for certain conditions. This machine, with some modifications, can be used for reseating these valves.—FRANK STROH.



PIPING CONNECTIONS

Indirect radiators, hung on basement ceilings, often complicate the pipe-work, especially that part of the piping which drains the radiator and vents the air. Unless the basement is a high one, the return is usually very close to the water line of the boiler, and the radiator is apt to become somewhat "water-logged" occasionally. For this reason, air vents which discharge directly to the atmosphere, should be avoided where possible.



Piping Connections.

The indirect radiator shown in Fig 1 is placed under a landing in a main hall entrance, and hence was below the steam supply and dry return of the vapor system. As shown on the drawing, an independent wet return was run just above the basement floor, having a check valve below the indirect radiator, and a separate air venting connection taken from the top of a tee at the return opening and carried over and connected to a thermostat type air line vent valve place at the dry return main.

—GEORGE DIXON.

A CONDENSER REPAIR

This repair was intended as a temporary job only, pending the arrival of a new condenser door, but it stood so well that, after a lengthy trial period, a new door was considered unnecessary. Fig. 1 shows the crack which developed, and its position. The length, as far as the writer remembers, was 8 in. to 12 in. A sketch was made, and a pattern roughed out, curvature and section, as Fig. 2. While this was being done, the holding-down studs in the vicinity of the crack were removed. The pattern was then "fitted" with red marking.

It should be mentioned that the pattern was of ample length, about 28 in. to 30 in. possibly. Having been fitted—or, rather, "bedded"—to the satisfaction of all concerned, it was taken to the foundry and a gunmetal casting made. This was again carefully fitted in place, marked off and drilled for the door studs proper, and also for an additional series of holes as shown.

The studs extracted were replaced by longer ones as necessary, and the adjacent side holes in door marked off from casting, and drilled and tapped. A liberal supply of red-lead was then applied and th

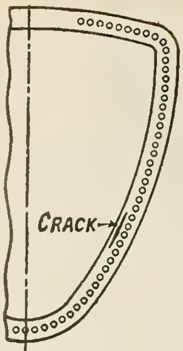


FIG. I.

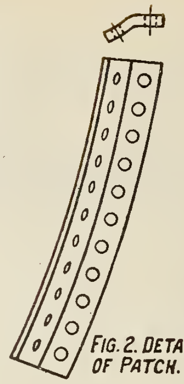

FIG. 2. DETAIL OF PATCH.

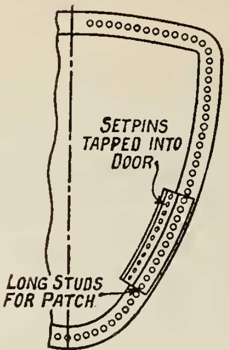

FIG. 3.

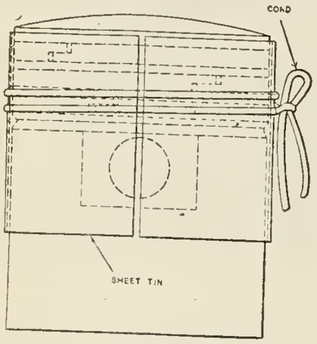
casting finally placed in position. The original nuts were used on the studs, and set-pins then securely pulled up into the adjacent side. This effected a very substantial repair.—FRANK GALLOWAY.

ASSEMBLING PISTONS

The writer read with great interest a description of a device for assembling pistons in cylinders which appeared in a recent issue of Power House.

The method described appeared to be a very good one, the only criticism being that different sizes of pistons would require separate sleeves. This fact, however, would hardly need to be considered except where a great variety of engines are assembled, as in repair shops handling general repair work.



A method that the writer has found very satisfactory is as follows: Cut a piece of stiff tin such as used for canned goods to a length that will nearly but not quite encircle the piston. The width of this piece should be about two-thirds the height of the piston. The tin is wrapped carefully around the piston and rings after they have been cleaned and oiled ready to be assembled in the cylinder. A heavy cord is passed around the tin a couple of times and pulled tight in order to compress the rings. The string is tied in place with a single bow-knot as shown in the accompanying illustration.

As the piston is slid into the cylinder, the tin and string slide off at the lower end of the piston and are easily removed from the connecting-rod. This method keeps the piston clean and simplifies the work of assembling. The cost of the device is practically nil, and one piece of tin can be used for several sizes of pistons.—M.D.S.

CRANK CASE OIL

In crank cases or tanks from which oil s pumped through engines or other machinery, the oil sometimes becomes thick and gummy in the bottom of the tank and will not run out through the drain cock. Since it is not advisable to use waste or wipers to remove this thick oil, on account of lint stopping up the strainer, which is usually of fine mesh, one method of draining is as follows:

Drain off the oil that will readily run out and then pour considerable hot water into the case or tank and loosen the oil from the bottom with a stick, and the thick oil will float on top of the water. Then take paper of any kind and s the oil off the top. The water can then be drained off in the usual way.—G. UHL, Galt, Ont.

AMMONIA COMPRESSORS

The ammonia compressor should never be started until the engineer has made sure that the discharge-valve line is open. He should not forget to turn the water on the condenser coils before or immediately after starting the compressor.

The head or condenser pressure should be watched upon starting the compressor, as it will warn the engineer if things are wrong.

The suction valve should not be opened hurriedly upon starting, especially if the machine has been shut down for a long time without having the expansion coils and suction lines pumped out. The operator should keep his hand on the discharge valve if possible. If it gets cold suddenly and if the discharge valve and compressor work noisily, liquid is likely coming back with the gas, and the suction valve should be closed off until the machine begins to warm up. If there is a slamming in the cylinder, the suction valve should be closed until the noise stops. This slam is in most cases due to the presence of some liquid ammonia coming in from the suction line. —H. STEVENS.

KEEPING BEARINGS COOL

We had started up a new large refrigerating unit and it had not been in operation long before we spotted one of the bearings running hot. We tried several adjustments but it did not seem to relieve matters, and we, therefore, sent for the erecting man to return and give the matter attention.

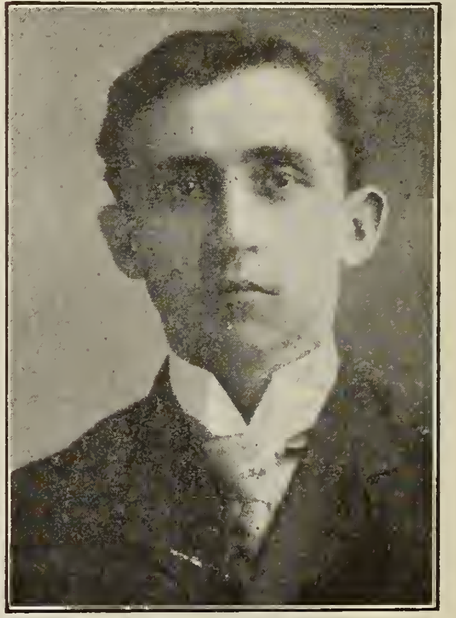
In the meantime our load forced us to keep the unit going, and as a means of affording temporary relief we tried a scheme recommended by a friend.

We took a piece of old pliable belting about four feet long, placed it over the shaft and laced the two ends together. A tub of water was then set below so that the lower end of the belt was submerged in it for about six inches. The rotation of the shaft and the adhesion of the belt to it resulted in the turning around of the belt, and, naturally, as it turned it carried a certain amount of water up with it, just enough, it turned out, to keep the bearing from heating up too much.

This very simple scheme can probably be used to advantage in other ways where it is desired to feed water or some other liquid continuously to a heated bearing, without constant attention and without making a lot of mess and slop in the engine room—WALTER HUDSON.

C. A. Maguire, chairman of the Board of Control, Toronto, is receiving tenders until September 3 for a three-motor travelling crane, hoist and appurtenances.

The Clark Gold Mines Corporation, with office at Halifax, N. S., have taken over the whole of the interests of the Montague Goldfields, Limited, and the Metals Recovery Company of Canada, Limited. At the present time the entire property and mines are in the process of electrification. A new power plant is being installed, and will consist of a fifty stamp mill with 1,500 pound batteries, and 20 concentrating tables. The present plant is costing approximately $100,000. E. S. Romilly Smith is the general manager of the company.



Joseph Grier.

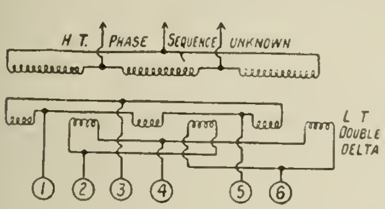
Joseph Grier, the engineer in charge of the plant of the Northern Rubber Co., Guelph, Ont., has been a subscriber to Power House for many years, and would not miss a single issue.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

PHASE ROTATION

Will you analyze the accompanying diagram and state if the low-tension leads of the transformers when connected to a six-phase rotary converter in the manner indicated by the numbers of the leads would be correct, and uphold a six-phase sequence? The high-tension phase sequence is unknown. The numbers are considered by the querist to be incorrect, and he would be glad if you would say how the low-tension leads should be connected to rotary slip-rings.—HYDRO ENGINEER.



Answer: The diagram accompanying the query is not correct if the numbers on the L. T. leads of the transformer refer to the slip-rings, assuming the rings are numbered from left to right, or vice versa. Apart from this, however, the internal connections of the transformer are right. Phase sequence has little bearing on the matter.

There seems to be haziness in the minds of some engineers regarding the production of a six-phase supply from a three-phase, and perhaps a little explanation on this point will enable "Hydro Engineer" to see the reason why the internal connections of the transformer being correct, H.-T. phase sequence does not affect the production of a six-phase supply to the converter, except as regards the direction of rotation of the rotary armature.

Fig. 1 shows the arrangement of connections for delta-double-delta in perhaps a rather clearer manner, though the arrangement and numbering of leads is exactly the same as in the diagram given in the query. The arrows indicate instantaneous directions of voltages in the windings. The vector diagram for the H.T. winding is the triangle A B C.

Consider the first upper delta secondary system 1-3, 3-5, 5-1. The vector diagram for this system is the triangle 1, 3, 5. The currents flowing to the rotary slip-rings through the tapping points 1, 3 and 5 are the resultants of the currents in the two windings terminating at each of these points and are denoted by the dotted vectors pointing outwards from them. These vectors are 120 electrical degrees apart and constitute a three-phase system. To obtain a six-phase system a further three vectors angularly displaced midway between these are required. Such vectors are produced by the second delta system, by virtue of the reversal of the internal connections of this delta with regard to the upper system. The reversal results in the dotted vector triangle 6, 4, 2. It should be noted that the sense of direction round this triangle having regard to the arrows, is opposite to that of triangle 1, 3, 5, but the phase sequence is the same in both triangles, *i.e.*, clockwise when the primary sequence is A B C.

Inscribed in Circle

If the two triangles 1, 3, 5 and 6, 4, 2, be inscribed in a circle, the currents in the rotary slip-rings are denoted by the six radial vectors, those of one delta system directed radially outwards and those of the other system directed radially inwards, and it is these vectors which constitute the six-phase supply. The vector diagram in Fig. 1 is the key diagram for delta-double-delta supply, but obviously any arrangement of transformer secondary windings resulting in the production of the six radial vectors will give a six-phase supply. The diameter star connection, shown in Fig. 2, is widely used on rotaries where a neutral point for a three-wire system is required. Only three secondary windings are used in this connection.

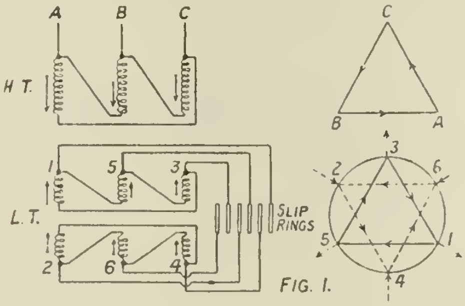


FIG. 1.

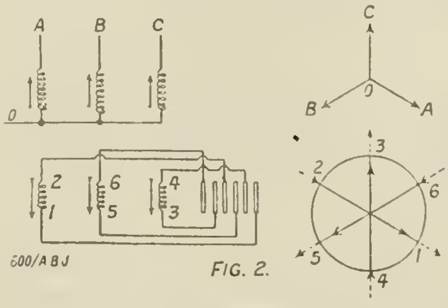

FIG. 2.

Phase Rotation.

In the case in point it would be best to obtain from the rotary makers a diagram of connections. Failing this, the connections can be checked by careful inspection, though it may be a tedious job owing to the multiplicity of tapping and equalizer rings on the rotary armature. The following tests should be carried out:

(*a*) Before connecting transformers to rotary.—First check each secondary delta system, by opening one corner of the delta and testing for voltage across the gap. Correct connection gives zero reading; a reversed coil gives a reading across the gap which is double the normal voltage of one coil. Next test for polarity. Temporarily join terminals 1 and 6, and test voltages across.

Where E represents the normal voltage of one secondary winding—

5-2. Reading should be zero.
3-4. Reading should be √3E.
4-5. Reading should be E.
3-2. Reading should be E.

If these check out correctly, the transformer is ready for connection to the rotary slip-rings. The leads from the transformer, numbered in accordance with Fig. 1, should be connected to the slip-rings in the order 1, 6, 3, 2, 5, 4, commencing with No. 1 lead on the left-hand ring and finishing up with No. 4 lead on the right-hand ring assuming that the armature tappings are taken to the slip-rings in cyclic order, which, so far as the writer is aware, is standard practice. As an additional safeguard, however, the rotary might be inspected to determine whether this is so. There will be six tappings per winding pitch, and the order of connection of these tappings to the slip-rings should be noted.

It is practically certain that the order of connection is as indicated, so that under normal conditions the same voltage exists between any two adjacent slip-rings.

STEAM-BOUND PUMP

How can the water end of a boiler feed pump be prevented from becoming steam bound?—R. WILSON.

Answer:—A feed pump may become steam bound from hot water of the boiler being forced back through the pump to the suction from leaky boiler-feed check or stop valves and leaky pump piston and valves.

The trouble from that cause is not likely to be serious if the boiler-feed line stop valve is shut down hard when the pump is not in use, and if the pump when in operation is run fast to overcome the leakage. When pumping hot water, the pump may become steam bound, because the suction head is not great enough for filling the pump chamber without reduction of pressure below the boiling point of the water corresponding to its temperature.

The reduction of pressure that results from friction of flow to the pump will be reduced by running the pump slower. If that is not practicable, the suction water must be supplied to the pump under a greater head, i.e., by lowering the pump or raising the level of the suction water.

The loss of suction head will be greater, the smaller the size and greater the length of the suction line. Unless the suction water is supplied under head and the suction line is short and of full size of the inlet provided on the pump, trouble is likely to be experienced in pumping water warmer than about 150 deg. F. and about one foot additional. head will be required for each 5 degrees higher temperature of the suction water.

WATER IN 10-INCH PIPE

What is the velocity of water flowing through a 10-in. iron pipe where the pressure at points in the line 75 ft. apart are 20 and 17 lb. per sq. in.? —O. W. E.

Answer:—The rate of flow corresponding with the drop of pressure would depend on the roughness of the pipe and on the number of bends, fittings or obstructions; but assuming that the pipe is fairly clear and straight, based on experiments, this loss of pressure, namely, 3 lb., or loss of head of 3 × 2.3 = 6.9 ft., would be due to discharge at the rate of about 3,600 gal. per min., which would correspond to a velocity of 882 ft. per min.

This estimate is based on the assumption that the drop of pressure is correctly taken at 20 — 17 = 3 lb., and it should be borne in mind that estimates of pipe flow cannot be regarded as closer than 5 per cent. because of the difficulty of knowing whether the pipe surfaces are in the same condition as pipes on which the formulas have been constructed.

QUALITY OF STEAM

Where a non-condensing engine under a stated load is guaranteed to have a steam consumption of 24 lb. of dry steam per indicated horsepower-hour supplied at stated pressure, and the actual quality of the steam used is only 96 per cent. dry, what consumption of steam of quality actually supplied would fulfill the guarantee?—A. M.

Answer:—Each pound of the wet steam as supplied would consist of 0.96 lb. of dry steam and 0.04 lb. of water; and the guarantee would be fulfilled for consumption of 24 ÷ 0.96 = 25 lb. of wet steam per indicated horsepower-hour. The consumption of actual dry steam will be the same for any reasonable variation of the proportion of moisture present. Experiments have shown that introduction of water in proportions from 1 to 42 per cent. is practically without influence and that the water remains inert, neither helping nor hindering the dry steam consumption.

APPARENT CUTOFF

In operation of a steam engine what is meant by "apparent" cutoff and "real" cutoff?—LONDON.

Answer:—Cutoff is the event during the stroke when the steam-admission valve has just closed, preventing further admission of steam, and the fraction of stroke that is completed at the time cutoff occurs is called the "apparent" cutoff.

During the remainder of the stroke the piston receives the expansive force of the volume of steam in the clearance space plus the volume contained in the space swept by the piston from the beginning of the stroke to the point of cutoff, and the "real" cutoff is the ratio of the sum of these volumes to the volume swept by a complete stroke of the piston plus the volume of the clearance.

Hence, to find the real cutoff, add the clearance, expressed as a percentage of the volume swept by a complete stroke of the piston to the apparent cutoff expressed as a percentage, multiply the sum by 100, and divide the product by 100 plus the clearance percentage.

FAN CAPACITY

What would be the relative size or capacity of a fan required for mechanical draft or induced draft?—A. M.

Answer:—The relative capacities depend on the conditions. For a given boiler the volume of gas passing through an induced-draft fan is much greater than would be handled by a forced-draft fan, depending on the draft pressure the temperature of the gases, and to some extent on their analyses. Under conditions of average plants the fan capacities required for induced draft are about 50 per cent. greater than for forced draft.

HUNTING GOVERNOR ACTION

What causes the irregularity of speed following a change of load of an engine? —A. STEVEN.

Answer:—When there is a change of load, there is an alteration of speed of the engine and the governor cannot act immediately, because it only can operate after a change of speed has occurred. Then a change in position of the governor does not affect the change of speed of the engine immediately, both on account of the inertia of the moving parts of the engine, which has the effect of resisting a change of speed, and also because of the energy contained in the steam that has passed the control of the governor.

In case of a throttling governor the steam chest is filled with steam at the time the change of speed begins, and if the governor acts upon the cutoff its opportunity for controlling the speed has passed it cutoff has occurred.

Hence there is a time lag between the governor and the engine speed. If the governor is too sensitive, then by the time the change in engine speed has had full effect on the governor, it is forced into a position of over-control; that is, a position beyond that which is necessary to bring the engine speed back to normal. The engine speed then begins to change in the opposite direction and for the same reasons the governor forced into a position of over-control in the reverse direction.

A state of oscillation is thus set up, which causes the speed to be first too high and then too low—a condition known as "hunting," which can be reduced to a minimum by not having the governor too sensitive and also by dashpots attached to the governor in such a manner as to dampen its motion.

WATER HEATING SURFACE

I am unable to find a good formula for determining the steam coil surface required in water heating tanks. The known conditions are: pounds of water to be heated per hour; initial and final temperature of water; steam pressure. Coils to be submerged in tank, consequently the velocity of the water will be about nil.—J. SMITH.

Answer:—We have before us a pocket size catalog called "The Ideal Fitter," and in it there appears a diagram showing the square feet of steam pipe coil while heating water in tanks.

On this diagram three hyperbolical curves are drawn, the first for galvanized or blank pipe, the second for brass pipe and the third for copper pipe. The vertical column or ordinate at left shows temperature differences ranging from 0 to 200 deg. F., while the horizontal column or abscissa shows 0 to 140 lbs. steam condensed per hour per square foot of coil surface. It is stated that "these curves are plotted from a large number of tests made with these pipes placed vertically in a tank of water." It is also added that the curves show only about 80 per cent. of the real condensing capacity, 20 per cent. being reserved due to so much lower efficiency to be expected in actual practice.

Thus in a vertical pipe the entrapped air may be at top, while in a regular horizontal coil the air will retard the exchange of heat.

Curves Start at Zero

At no difference between steam and average water temperature 0 lb. steam will be condensed per hour per square foot of coil surface. Hence all three curves start from zero. Then they spread out as indicated by the following:

Deg. temp. diff.	50	100	150	200
Lb. steam condensed				
Galv. or black pipe ..	7.5	18.3	32.5	48.8
Brass pipe	12.5	38.	76.5	128.
Copper pipe	14.2	43.8	88.	148.
B.t.u. per sq. lb. hour through black pipe ..	7270	17760	31500	47300
Same, deg. diff.	145.5	177.6	210.	236.8

At higher temperature differences the water is in stronger circulation than at low temperatures and this results in an increased rate of heat transfer, as is apparent from the last line in table.

Ratio More Favorable

While in the above table the steam condensing capacity of the galvanized iron and black pipe is rated at but 42 per cent. of that of copper pipe, the actual ratio must be more favorable than this. In E. Hausbrand's book "Evaporating. Condensing and Cooling Apparatus," it is stated that in good practice the heating capacity of iron pipe is taken at 0.75 that of copper tubing, cast iron at 0.50, and lead at 0.45. He also points out that the air within the steam may greatly hinder the transfer of heat, hence if the duty of the coil surface is to be increased this can be done by providing a small vent and let a little steam escape with the air into the water, if permissible. Efforts should be made to obtain a high steam velocity, small pipes being much more efficient per square foot than large pipes; in large pipes the steam in the coil not coming in contact with the wall of pipe. The shorter the pipes the better, because in a long pipe the pressure and steam temperature drop considerably toward the end.

Drain Condensed Steam

The pipes ought to be inclined to help drain the condensed steam. If the group of coils could be arranged on one side of a vertical partition, the circulation of the water to be heated could be admitted, the warm water rising above the coils and descending by gravity on the other side of the partition. In some cases vertical sheets of metal are placed in a tank, the water entering at one corner of the flat tank and being compelled to flow zigzag through the tank to the opposite outlet. In this way the water flows through the tank with some velocity which greatly favors the rate of heat transfer.

Of course, where all the steam may be injected (through small holes in pipes) directly into the water only enough piping is necessary to accommodate the required number of holes. The smaller and more scattered the holes, the less the crackling noise caused by rapidly condensing steam.

The following example is worked out in the catalog already mentioned:

Surface required to condense 500 lb. steam per hour in galvanized or black pipe coil immersed in the water of a storage tank:

Temperature of steam in pipe, 220 deg. F.

Initial temperature of water, 40 deg. F.

Final temperature of water, 160 deg. F.

Hence mean temperature of water, 100 deg. F.

Temperature difference between steam and water, 120 deg. F.

The curve on chart shows that with 120 deg. difference each sq. ft. of galvanized coil surface condenses 24 lb. steam per hour. Incidentally the brass pipe curve shows 51.5 lb., and the copper 59.5 lb. condensed. For 500 lb. steam it requires 500/24 or 20.84 sq. ft. galvanized or black surface.

If we assume now that the heat given up per lb. of steam is only 970 B.t.u., then 24 lb. steam gives up 970 × 24 or 23,280 B.t.u. per sq. ft. black surface, per hour, with 120 deg. difference, which is equivalent to 23,280/120 or 194 B.t.u. per deg. difference.

This factor or coefficient is usually designated by the letter k.

OIL BURNERS

I am operating a 100 h.p. horizontal return boiler equipped with an oil burner. The results so far have been very poor. The building is new and the equipment the same as furnished by the contractor.

The only part of the boiler that was receiving any benefit of the heat was that section directly above the fire. The brick arch was built to within 9 inches of the boiler leaving 11 feet of combustion chamber 5 feet 6 inches high under the boiler, which in my opinion is too large.

Recently I pulled down the brick arch and built the combustion chamber up to within 20 inches of the shell, and put baffles in at intervals as far as the back walls to hold the gases to the boiler shell. In addition the original burners furnished have been replaced with one of my own design, a straight oil and air burner.

Oil is fed to the burner at 24 lb. pressure and the air between 5 and 6 ounces, supplied by an electrically driven fan.

Would it be advisable to heat the air and if so what would be the cheapest method of doing so? Would it be of any advantage to heat the oil and increase the pressure? The steam pressure carried is never more than one pound.

A. WRIGHT, Toronto.

Ans.—You do not give sufficient information for an engineer to give a definite opinion as to whether the change would be of any real benefit. In the first place cutting down the size of the combustion chamber will cut down radiation losses and if the brick work around the boiler is in bad condition the chance for air filtration will be less. Oil burners do not require as large a combustion space as coal, but care must be taken to keep it large enough to prevent the oil flame inpinging directly against the shell or there will be danger of blistering.

With the original burner installed, if insufficient air is provided with the oil, and an excess admitted at a point some distance from the burner it is impossible to secure proper combustion. The new burner installed by you will give good results if you are securing proper atomization and adjust the supply of air. The advantage of oil over coal is that the amount of excess air with the oil can be cut down to a minimum; some engineers do not take the full advantage of this fact.

CLEANING BOILERS

We have a 60 h.p. locomotive type boiler which is used for stationary purposes. The boiler has so much sand and muck in it that it is impossible to make a good job of cleaning it. At present there is a coating of scale about 1-16 inch thick on the tubes and the shell. It is not possible to get at the scale to remove it, the only way that we can attempt to clean the boiler is by washing monthly.

No compound is used, would it be advisable to use the formula given on page 39 in the August issue of Power House?

GEO. KARAMADUK,
Montreal.

Ans.—The compound referred to has given a fair degree of satisfaction in the boiler in which it is used in Toronto according to the engineer in charge, E. Golightly, but it does not follow that it would do the same for your boiler. The proper procedure is to find out what is causing the scale, then use a suitable compound to counteract the scale forming compounds in the water. Sodium carbonate (washing soda) and sodium hydroxide (caustic soda) are the main ingredients in many of the boiler compounds used by prominent engineers.

CHARCOAL DEODORIZERS

Can you advise me where I may obtain information in regard to the removal or absorption of odors from ice chests, etc., by the use of charcoal or any other means.

Have any articles been written on this subject that you know of?—ENGINEER.

Answer:—It is a well-known fact that charcoal has the property of absorbing odors. Wherever ice is being made from distilled water, which is usually derived from steam exhausted by engines, pumps, etc., charcoal-filled filters are used for absorbing the gases contained in the steam, as well as the odor imparted by the oil necessarily used for lubricating the steam cylinders. Reference to this practice may be found in all books treating of artificial ice making.

If it is desired to remove odors from ice chests, simply spread out a one-inch thick layer of flake charcoal on wire netting and replace with a fresh charge as often as required, perhaps once a week, depending upon the state of the chest and the size of filtering area.

By an "ice chest" is understood a refrigerator built like a trunk, the ice being as low down as the provisions or perishable goods. This makes a cheap ice box in every sense of the word. This type should be avoided where possible because it has no proper circulation.

Since cold air is heavy it should be given a chance to drop a perceptible height, crowding out and upwards the warm air which can then deposit its moisture as well as odors upon the melting ice. Unless the air can circulate thus up and down there will be large differences in temperature between points near and remote from the ice. The uncooled perishables decay and emanate objectionable odors. The lower the air temperature the less is the tendency to cause odor. In a properly built sanitary refrigerator the ice or source of refrigeration is always placed at the top, with amply large down-ducts and up-ducts to promote and guide the circulation of air. In that case no deodorizing agents are necessary.

Power Plant Supplies a Feature of Exhibition

Lack of Suitable Foundations Prevents Actual Operation of Heavy Equipment—Power Plant Supplies Include Traps, Valves, Transmission Machinery, Belting, Oil Engines, Fire Brick and Grates

MACHINERY HALL at the Canadian National Exhibition is full of exhibits of interest to the power plant engineer this year.

At one end is a large Diesel engine operating full blast, fascinating every visitor with the thrust of its mighty piston and the swift revolution of the mammoth fly wheel, while in another section there is a miniature Niagara flowing from a pump that operates continuously.

Several firms exhibiting heavy engines and equipment were unable to show the equipment in actual operation.

Among exhibitors noticed on a tour of the exhibition grounds were:

The W. R. Sexton Boiler Setting Co., with W. Russell Sexton explaining to engineers the importance of proper brick work and Nonpareil shaking and dumping grate bars.

Cole automatic return traps of various sizes being explained by Bruce H. Mowat.

The Beardmore Belting Co., with a complete line of leather belting, Frank Inrig in charge.

The Farrfhern Steam Service Co., represented by J. E. Farrell, agents for the Morehead steam trap and steam specialties.

Jones & Moore Electric Co., with W. Dalton in charge, Century motors.

The D. K. McLaren Co., with a full line of mill supplies, leather and canvas beltings; W. S. Hamilton in charge of booth.

Dodge Manufacturing Co., exhibiting general transmission machinery, including pulleys, shafting, bearings and hangers; W. B. Burrows in charge.

The John T. Hepburn Co., of Toronto, displaying power plant auxiliaries, compressed air furnishing the energy for driving the following: a duplex steam pump, a simplex boiler feed pump, a high pressure vertical ram type pump, and a small vertical steam engine. One 3-inch double suction centrifugal pump direct connected to a 5 h.p. motor, delivers three hundred gallons per minute against 40 foot head, the other a one-inch single stage delivering 35 gallons per minute against the same head. H. Skitch, chief engineer of the company, is in charge.

The Fairbanks-Morse Co., in addition to transmission equipment, belting, both leather and balata, displaying a semi-Diesel heavy oil engine. According to F. W. Evans, with fuel oil at 9c a gallon the cost for fuel with the semi-Diesel engine is about ½c per h.p. hour. This engine has solid injection, variable stroke fuel pump and air starting.

The Link-Belt Co., represented by N. A. Weston, show a machine called a "paradox" for showing the action of the silent chain in passing over the gears. In addition they demonstrate chains for the transmission of power and the handling of materials.

C. R. Peckover, of the Peckover Steel Co., shows boiler tubes, stair treads and checkered floor plates.

Westco Pumps display in charge of C. Templeton. This type of pump is of special interest to engineers interested in oil burning equipment. A fire fighting pump direct connected to a 4-cylinder gasoline engine is also on view.

Mid-West Canada, Limited, of Montreal, show air filters. The Dominion Engineering Agency, 24 Adelaide St. E., are the Canadian representatives. D. M. Fraser in charge. In addition they handle electric equipment, R. & M. motors, circuit breakers, high tension equipment, Sundh industrial control, and Rawlplugs.

Imperial Oil, Limited, with E. A. Olver in charge exhibit a complete list of oils and greases.

Albany Pump Co., 120 Adelaide St. W., showing the Albany water seal rotary pump. A. W. Bennet representative.

Keighley Gas & Oil Engine Co., of Keighley, England, with W. S. Haggas, 131 Front St., Toronto, general manager for Canada, demonstrating oil and gasoline engines. A 50 h.p. Imperial Keighley semi-Diesel heavy oil engine driving an air compressor which furnishes air to all parts of Machinery Hall. This engine is of heavy duty horizontal type with solid injection. The gasoline engine field is represented by the following: A four cylinder four cycle 35 h.p. engine direct connected to a 21 K. W. generator; an Imperial 8.5 kerosene-gasoline engine direct connected to a 750 gallon per minute pump running at 750 r.p.m. In addition there are several smaller engines.

Ingersoll-Rand have a compressor connected to the Keighley heavy oil engine.

The Dominion Belting Co., with E. Kinrade in charge show canvas belting.

Waukeska Motor Co. have several engines on display in their stand in the Arena, including a 50 h.p. power unit on skids suitable for fire protection or industrial uses. J. J. Swain is the Canadian representative.

The James Morrison Brass Co. are in the Industrial Building, with Arthur Betton in charge and have a very complete exhibit of brass goods, including steam traps, gauges, both indicating and recording, injectors, iron and brass body valves, whistles, gong bells, oil cups, water gauges, gauge cocks, and a general line of engineers' supplies.

Vickers-Petter have two exhibits this year, one in the Pure Food Building showing some of the lines made by them, including forgings for engine crankshafts and small gasoline and oil engines; the other at the eastern entrance showing a semi-Diesel heavy oil engine in operation. This engine is rated at 60 h.p. at r.p.m., compression pressure 150 lb. per sq. in., using solid fuel injection. The Petter Oil engine made in sizes to 25 h.p. has an interesting device for cold starting without the use of compressed air; a cartridge is screwed into the head and ignited, the engine then starts from a few turns of the crank handle. Canadian Vickers of Montreal are the agents for Canada. R. S. Griffith is the sales manager.

Refrigerating Engineers, Limited, of Toronto, Canadian distributors of Frick refrigerating machine have in operation a two-ton ammonia compression machine of the combined unit type. J. V. Turner is assisting in explaining the good points of the unit.

Ruston and Hornsby, Limited, of Lincoln, England, showing a 60 h.p. airless injection cold starting oil engine. The engine is of the horizontal type fitted with air starting equipment. Fuel consumption under ordinary conditions is claimed to be about .42 lb. per B.h.p. hour. Laurie and Lamb, of Montreal, are the Canadian distributors. Albert Laurie is in charge, assisted by C. C. Cottrell.

Power Notes

Chas. Warnock, Montreal, has been elected president of the Robt. W. Hunt Co., Ltd., inspecting and testing engineers, Montreal.

Clarence McNaughton Steeves, B.Sc., Sussex, N. B., a member of the Engineering Institute of Canada, has been appointed construction engineer of the New Brunswick Hydro Commission.

E. Ibbotson Leonard, president of E. Leonard & Sons, boiler manufacturers of London, Ont., has been elected a director or the Canada Trust Company.

Choosing Boilers for a Huge Municipal Plant

Advisory Committee Sustains Recommendation of Detroit Public Lighting Commission That Contract for Cross Drum Water Tube Boilers be Given Babcock & Wilcox Co.

THE report of W. B. Mayo, chief engineer of the Ford Motor Co., T. H. Hinchman, of Smith Hinchman and Grylls, and J. C. McCabe, head of the City Research Bureau, the members of the special committee appointed by the Public Lighting Commission of Detroit to decide the merits of the different boilers on which tenders were made for the new municipal station in the Motor City, an installation consisting of four 20,000-kw. turbo generators, each served by two boilers designed for 350 but to be run at about 300 lb. and 200 deg. F. superheat, using powdered coal, will interest Canadian engineers.

The report, which was made public last week, sustains the recommendation of the commission that the contract be awarded to the Babcock & Wilcox Co., the second highest bidders on the eight cross drum water tube boilers specified.

The bids follow, but a reduction in the size of the boilers to 13,700 sq. ft. reduced the successful bid by $40,128, making the price $331,456 for the eight boilers, and $66,960 for the superheaters.

ELECTRICAL POWER

(Continued from page 34)

Single-phase operation of a polyphase motor will cause the motor to fail to start and produce a dangerous temperature in the current-carrying phase; if the single-phase operation occurs during running conditions the motor may burn out due to the excessive load, or break down. The effect of unbalancing either phase, voltages or angles is to increase the heating and decrease the maximum output or torque. This effect is very important, as a 15 per cent. unbalancing on a standard motor may nearly double the heating.

Surging on Lines

Small motors may be thrown directly on the line, but where large motors are treated in this manner there may be serious surges on the line and unless the motor windings are extremely well braced, there is apt to be injury to the insulation due to the crushing forces of the magnetic reactions.

It is recommended that an oil switch be used for all motors of 100 h.p. capacity or over; below this size it is recommended that fuses be checked daily with pilot lamps. In this connection it is to be noted that a line of push button, magnetic switch starters have been brought out and can be purchased at moderate cost. These are applicable for three-phase motors rated from one to ten horse power and provide phase failure protection as they open all three legs of the circuit by means of the three pole Magnetic Switches.

Power Notes

The Foundation Company of Canada, Limited, Montreal, have been awarded the contract for the construction work in connection with the Southern Canada Power Company's new power development at Hemming's Falls, near Drummondville, Quebec. The preliminary work is to be started at once.

A. T. Croft, secretary Nova Scotia Power Commission, Halifax, N.S., will receive tenders until September 10, 1923, for the construction of a 66,000 volt single circuit transmission line from Hopewell, N.S., to Stellarton, Pictou Co., N.S., and a 13,200 volts transmission line from Stellarton to Pictou, Pictou Co., N.S.

The Broadfoot Electric Company, Ltd., capitalized at $200,000, has been incorporated for the manufacture of a new type of battery recharging machine, and has secured temporary quarters on Thames Street, Chatham, Ont., for manufacturing and assembling purposes.

Tenders have been called for by the secretary-treasurer of the Gladstone School Board, Gladstone, Ont., for the provision and installation of a two-pipe Dunham system steam heating plant.

Obituary

Hertha Ayrton, of Lansing, Sussex, the only woman member of the Institution of Electrical Engineers, died on August 26, 1923. She was the wife of Professor W. E. Ayrton, and invented and constructed a line divider, and ably assisted in the completion of a series of experiments on the electrical arc invented by Professor Ayrton. In 1915 she invented an anti-gas fan, of which more than 100,000 were used on the allied front during the duration of the war.

Eliminating "I guess" "I believe" "I suppose" from the Boiler Room!

Put your firemen in a position to know *what* to do and *how* and *when* to do it. It will mean far greater efficiency in the boiler room and save you money. Don't force the firemen to go by "guesswork." A daily chart from the Hays Automatic CO_2 and Draft Recorder will supply the information at the time it is needed.

The Hays Automatic CO_2 and Draft Recorder (Model B) is the last word in being the most practical and simple in construction and operation. Any ordinary unskilled laborer can operate it. The Standard Recorder will chart the percentage of CO_2 contained in the waste gases from the boiler furnaces, stills, kilns and also the draft over the fire. The standard range is 0-20% CO_2 and 0-1 inch water draft. Extra attachments can be provided for:

1. Double Draft Record. By having a record of draft over the fire and another of draft in the last pass, the draft loss or "air flow," as it is sometimes called, is indicated by the "spread" between the two draft records.
2. Record of CO or Unburned Gases can be furnished as an additional attachment when required.
3. Record of Stack Temperature to show whether the heat is being absorbed or wasted up the stack.

All the above records can be placed on one and the same chart. Special recorders are furnished for SO_2 or other acid gases and CO_2 recorders of any range other than 0-20%, on short notice.

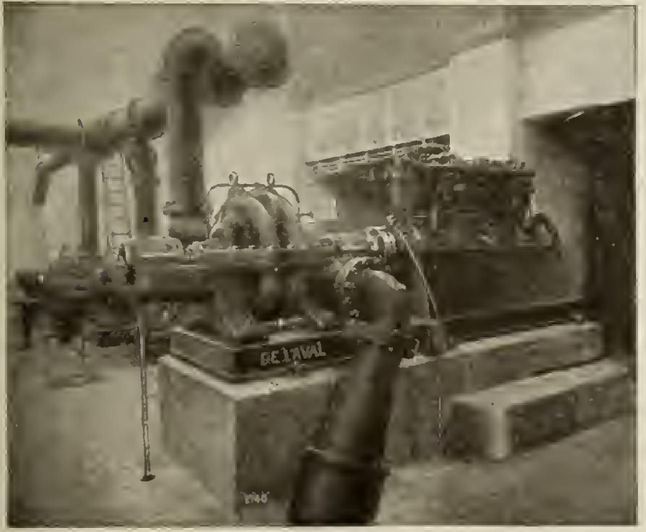
HIGH GRADE POWER PLANT AND PUMPING EQUIPMENT

Orillia, Ont., Selects De Laval Pumps for Safety and Economy



THREE DE LAVAL centrifugal pumps installed in the water works pumping station of the City of Orillia, Ont., are shown herewith. The two-stage 8-in. pump in the foreground is driven by a gasoline engine, and has a capacity of 1,440 gal. per min. against 325 ft. head. The two De Laval pumps in the background are driven by electric motors. Where cheap electric power is available, this type of plant combines low cost, simplicity, and insurance against shut-down. The amount of attention required is very small, and practically no supplies are used.

The De Laval centrifugal pump is ideally adapted for both electric motor and gasoline engine drive. The starting torque is low and the power characteristic permits the size of motor to be selected to suit the normal capacity, resulting in lower power factor and higher efficiency in the driving motor. In many instances De Laval pumps are driven by self-starting synchronous motors, which can be used to correct the power factor.

State pumping requirements and ask for special publication B-100.

Miscellaneous

The McClave Brooks Company, Scranton, Pa., makers of McClave grates, stokers and combustion appliances, have appointed the Carbondale-Buffalo Co., Buffalo, N. Y., as their sales representative in New York state and Canada. Their territory will include that part of the state west of Rochester, and also the provinces of Ontario and Quebec in Canada. Henry J. Botchford is Manager of the Carbondale-Buffalo Company.

———

Installations of a No. 1 and two No. 5 Sims converters are being made through Arthur S. Leitch Co., Toronto, in the central heating plant in the county building at Walkerton, Ont.

———

The Spruce Falls Paper Co., are installing a No. 4 Nash hyter vacuum pump in their sulphide plant at Kapuskasing Ont.

———

Through the Arthur S. Leitch Co., Toronto, the town of Stratford, Ont., has purchased two Nash hyter air compressors for activating sludge work in sewage disposal.

———

The Hydro Electric Power Commission, North Bay, Ontario, have purchased through the Arthur S. Leitch Co., Toronto, a Norwalk air compressor of 1,000 lbs. pressure capacity.

———

The Goldie Construction Co., of Toronto, are the contractors for the new stack and tunnel in connection with the central heating system of the University of Toronto.

———

A 25 h.p. Allen heavy oil engine has recently been installed in the thermodynamic laboratory at the University of Toronto. The engine is specially fitted for test and experimental work.

———

John Laxton, 75 years old, 1457 Queen Street West, Toronto, died at his home on August 15. For the past fifty years Mr. Laxton was associated with the Consumers' Gas Company, Toronto, in the capacity of superintendent of street mains—in charge of all construction work. He was also government representative on the Toronto board of harbour commissioners.

———

The Doherty Natural Gas Company, Hagersville, Ont., held their third annual picnic on Wednesday, August 15, at Woodlawn on Lake Erie, three miles west of Selkirk. About 600 employees and friends were present, and the picnic was a big success in every way.

———

Tenders have been called by the Chairman of the Public Utilities, Winnipeg, Man., for the supply of all labor and material required in the erection of a building for a steam stand-by plant of the Hydro Electric System on Amy street, Winnipeg.

An agreement has been reached between the Toronto Harbour Commission and the Hydro Electric Commission concerning the removal of all Hydro towers along Sunnyside from the Exhibition grounds to the Humber River, Toronto, to a location further north, and preparations will be included to take care of the extra 110,000 h.p. soon to come from the Chippewa development. The estimated cost of the work is $75,000.

———

The Warwick Woolen Mills Co., Warwick, Quebec, are asking for prices on steam heating for the $60,000 factory being erected at Warwick.

———

Barr & Anderson, Vancouver, B.C., have been awarded the contract for installing heating equipment in the new city garage on Union Street, Vancouver.

———

Tenders have been called for the supply, delivery, and erection, of an electric travelling crane, capacity of main hoist 25 tons, in the power house of the Corporation of Winnipeg.

———

The Devoe Electric Switch Company, of Montreal and Toronto, have issued catalog No. 10 describing switches and other electrical appliances. The type of equipment illustrated is in the main for use in power plants and electrical stations. Knife switches of various types, motor control, electric time, enclosed safety type, indoor and outdoor disconnecting switches; sphere gap lightning arresters; choke coils; cartridge and high potential fuses; economy renewable fuses; switchboard accessories; panels; both dead and open front panel cabinets; and switchboards are some of the appliances dealt with at length.

———

Albert Forten, general contractor, Bagotville, Quebec, has been awarded the contract by the Bagotville Town Council for hydro power plant equipment, at $125,000.

Trade Catalogs

Tully's Gasification System manufactured by the Tully Gas Plants, Limited, of Millgate, Newark-on-Trent, England, is being installed at Belleville, Ont. The engineer in charge of the plant is William Cooke, an able "chief" and a past president of the C. A. S. E.

The Tully system consists of a generator, a wash box, a blower with primary and secondary air blast, a boiler for the injection of steam—fitted in such a manner that all the operations can be performed by one man.

The upper part of the generator consists of a vertical retort of a special design, surrounded with chequer work through which the exhaust gases pass during the period of the blow. At the base of this chequer work is the secondary air inlet.

The lower part of the generator is made like the usual water gas generators, but with special fittings.

The blue water gas produced in the lower part traverses again at a high temperature, the coal in the superimposed retort carrying away the volatile matter. Oil can be injected to further carburet the gas.

To mix Tully gas with ordinary coal gas: This may be done by allowing the hot gas to enter the foul main or it may be done in the relief holder, but before entering the relief holder, the Tully gas should pass through the scrubber.

Plants can be fitted with automatic clinkering and with waste heat boilers, using up the heat from the blow which would otherwise be lost. The steam generated is used for the steaming operations in the plant.

The B.t.u. quality of Tully gas made from coal relies upon the chemical composition of the coal used. The carbon as coke—going to produce water gas—and the hydrocarbons, producing methane and hydrocarbons present in the gas—so that when working at the maximum efficiency it is best to make a gas of a B.t.u. composition in a ratio of the carbon—hydrocarbon content of the coal used—carbon as coke will only produce a water gas of 300 B.t.u.'s and any B.t.u.'s over that may come from the gasification of the hydrocarbons of the coal.

The most economical method of working is to gasify the coal at its normal rate, and increase the B.t.u.'s as required by the use of gas oil.

POSITIONS WANTED

FACTORY SUPERINTENDENT—OR CHIEF Engineer is open for engagement. Have had wide experience in operating power plants and handling help in Canada. Apply Box 107, Power House.

ENGINEER, SECOND CLASS CERTIFICATE for Ontario, wants permanent position. Has had good all-round experience. Apply Box 111, Power House.

SELF-OILING HIGH SPEED ENGINE, SINGLE cylinder, 17 in. bore x 16 in stroke. Engine develops 200 H.P. when running at 235 R.P.M. with 100 lbs. steam pressure. There are two heavy leather belts 18 in. wide. The engine has two fly-wheels, each 78 in. diameter x 18 in. face. Apply Box 112, Power House.

POSITIONS VACANT

STATIONARY STEAM ENGINEER WANTED—familiar with water tube boilers and Turbo Blowers and Generators. Must be an all round competent man, capable of taking charge of plant of about 2,400 B.H.P. Must have first class certificate. State in first letter salary wanted, age, experience, and when you can report. Apply P. O. Box 720, Port Colborne, Ont.

BUSINESS CHANCES

SMALL BOILER REPAIR BUSINESS FOR SALE—with house property adjoining. No opposition. Located in a large manufacturing city. Reason for selling, owner in ill-health. Apply Box 110, Power House.

The LOGIC of INSULATION

¶ The idea of insulating heat is a relatively new one. It was only a few short years ago that the practice of insulating heated surfaces began to be recognized as a thing worth while.

¶ And yet the theory of insulation is based on a simple fact which has been recognized by man as far back as his cave dwelling days; namely, that to conserve heat it pays to cover heated surfaces with a "blanket" or protection of some kind. This realization prompted the first wearing of clothing.

¶ That is the reason why today we put on heavy clothing and storm overcoats in winter weather—to conserve our body heat and energy.

¶ The heat generated in a boiler or furnace or kiln is as susceptible to atmospheric conditions as our own human bodies. A protecting "blanket" of insulation over the surface (or installed within the walls) of such equipment as boilers, furnaces, kilns, ovens, etc., serves directly as a guard against heat loss through the walls and tops.

¶ SIL-O-CEL Heat Insulation is furnished as Brick, Block, Powder and Cement, and is readily adapted for the insulation of any type or shape of equipment.

¶ The cost of insulation with SIL-O-CEL is generally paid for in fuel saving alone within six to twelve months of operation, and these savings continue each year through the life of the equipment.

For Boiler Feed Water

Refinite makes scale impossible. It takes out the scale-forming lime and magnesia before the water enters the boilers. You save not only fuel, but the trouble, time and expense of washing boilers and replacing tubes.

A coating of scale even 1-50 in. thickness wastes 100 lbs. from every ton of coal fired.

Boiler Brand

The Simplest and Most Effective

FEED WATER TREATMENT

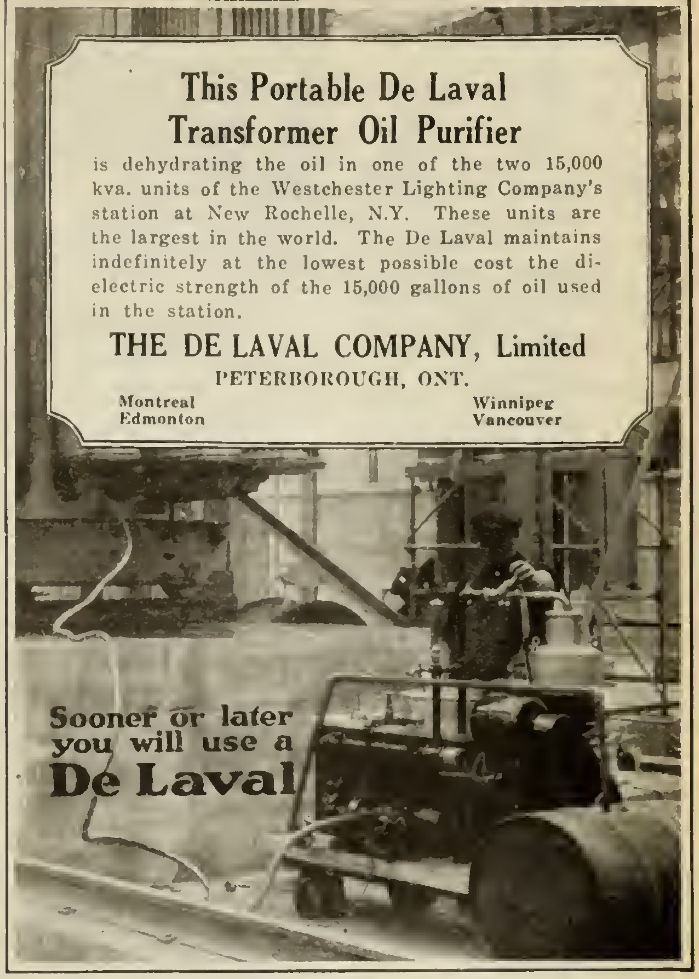
Silicate of Soda is the base of the majority of Boiler Compounds on the market—often made up under special names.

Boiler Brand is but one of our many grades of Silicate of Soda. It does the work of the most expensive compounds but as the engineer knows just what it is he can adapt it to varying conditions. Why bother with complicated treatments for the removal of boiler scale when the solution is so simple?

"Let a Technical Firm do a Technical Job."

G. F. Sterne & Sons, Limited
Chemical Manufacturers, Consulting Chemical Engineers.
Brantford - - Ontario

Toronto Dealer: W. M. Ismond, 48 Wells St., Phone Hill. 6868



This Portable De Laval Transformer Oil Purifier

is dehydrating the oil in one of the two 15,000 kva. units of the Westchester Lighting Company's station at New Rochelle, N.Y. These units are the largest in the world. The De Laval maintains indefinitely at the lowest possible cost the dielectric strength of the 15,000 gallons of oil used in the station.

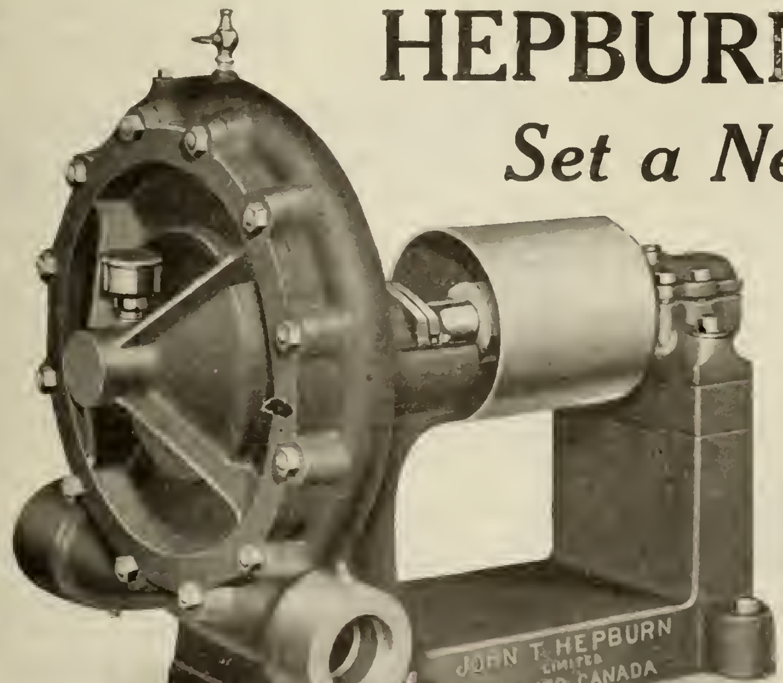
HEPBURN CANADIAN MADE PUMPS

Set a New Standard



The Hepburn Centrifugal Pump is not one of those "Old Stagers" which was designed 20 years ago and is still the same. It is, on the contrary, A Pump of modern design and up-to-date in every respect.

We also make Simplex and Duplex Pumps, Hand and Electric Overhead Cranes, Vertical Engines, Castings and Forgings.

ALLIGATOR

Scientific

STEEL BELT LACING

There is Science In Belt Lacing

ALLIGATOR teeth penetrate lengthwise of the belt, leaving the long burden-bearing fibers intact. Each tooth clinches down over its group of fibers, compressing them so firmly that there is no internal friction and wear at the belt end.

The sectional steel rocker hinge pin is the only metal pin that avoids wear to the joint.

Keep these vital features in mind when you buy belt lacing, for the cost of any lacing is nothing as compared to the cost of the belt on which it serves.

Just a Hammer to Apply It
"Never Lets Go"

AIR Engineering Service

The American Blower Company offers the co-operation of a competent Engineering department in the solution of any problem along the following lines:

- MECHANICAL DRAFT
- HEATING & VENTILATING
- GENERATOR COOLING
- AIR WASHING
- FANS AND BLOWERS
- STEAM ENGINES

American Blower service and mechanical equipment represents the development of forty successful years. Write for descriptive Bulletins.

FREE!

SMOOTH-ON NO. 3 — for making perfect screw-thread joints

For ________________

____

Pr. Hs. Sep. ________________

if you fill in here and return this tag

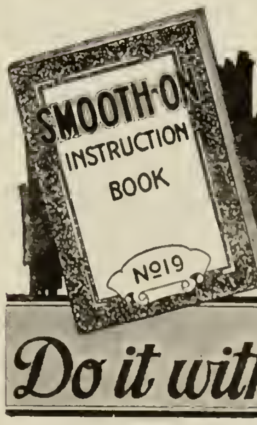
SMOOTH-ON No. 3 is much better than ordinary for screw-thread joint fillers.

Joints made with Smooth-On No. 3 stay tight because the metallic iron body can't dry out or shrivel from heat or time. Yet the joint can be taken apart if line changes become necessary.

In order that you may know this as well as we do, we urge you to fill in the tag as requested above and return so that we can send you the free sample.

You can get more at your dealer's in 1, 5 and 10-lb. gray-labeled tins, or, if he is out of stock, send us his name and we will see that you are supplied.

The Canadian Asbestos Co.
Dept. 52, Montreal, Que.



Get this book free!

This 144-page book of simple directions and diagrams will post you well on Smooth-On, where to use each grade, how to apply for best results and what to expect from the finished job. Mailed free if you return the tag.

Less Work—More Wear

THIS plastic furnace lining, in unbaked form, is pounded into place by anyone who can use a mallet. When vitrified, it forms a jointless, air-tight, gas-tight lining that resists temperatures to 3,100 deg. F. and that outlasts ordinary fire brick two to four times.

Plibrico is delivered only in steel containers of distinctive appearance as shown opposite. Warehouse stocks in principal cities. Your copy of the free fifty-page booklet shown opposite is ready. Ask for it.

MAGNOLIA

Magnolia Metal has been a widely used favorite for over a third of a century. Government tests prove it to be superior in bearing qualities to any other bearing metal, and its users know that it is uniform in composition, dependable in service, pours, melts, peens and scrapes in easily. For minimum bearing maintenance expense it will pay you to standardize on Magnolia Metal.

Genuine British Oak Tanned
Leather Belting

FLAWLESS back portions of specially selected hides are used for D. K. McLaren's Leather Belting. This, with any ordinary process of manufacturing belting, might seem enough to ensure strength and wearing qualities. But it isn't enough to obtain the perfection desired. In addition to care in the selection of hides, D. K. McLaren's Belting is all **British Oak Tanned.** This process imparts toughness to the leather. It gives it greater strength, greater durability and makes it as stretch-proof as leather belting can be made.

The quality reflected in D. K. McLaren's Belting, as a matter of fact, reduces transmission costs.

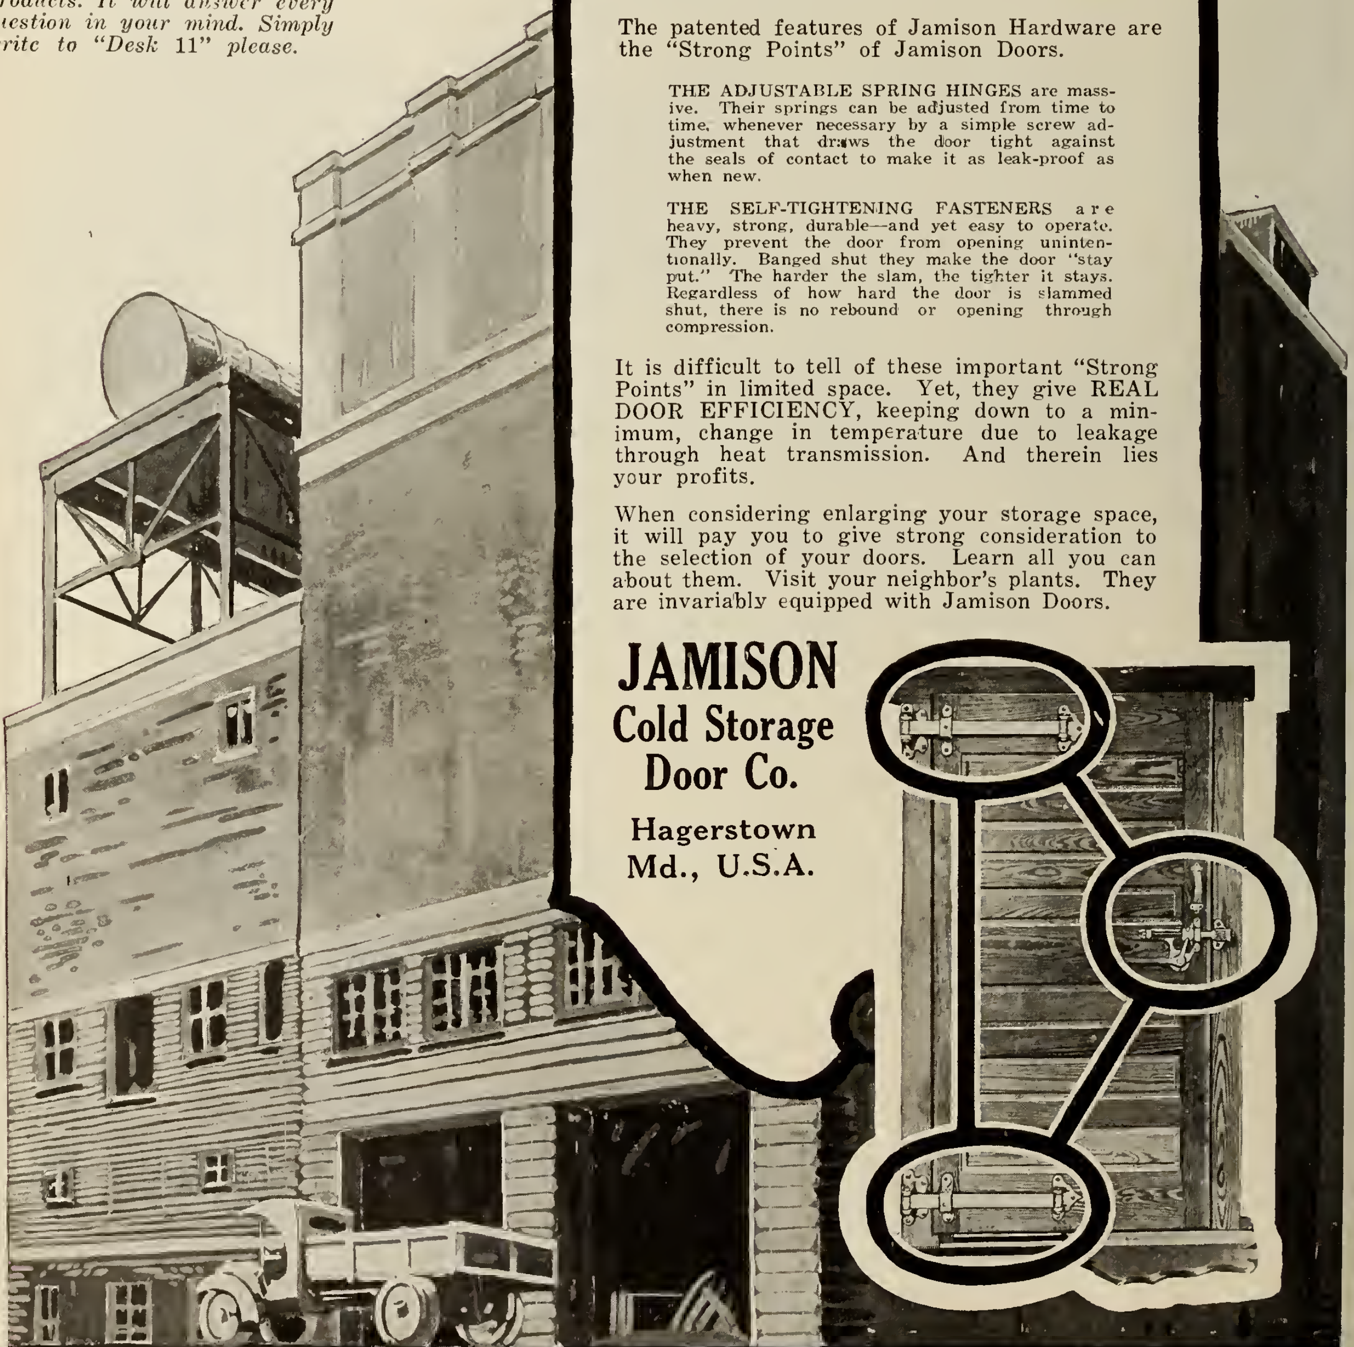
Jamison Doors

Our Catalog No. 10 gives a detailed description of Jamison Products. It will answer every question in your mind. Simply write to "Desk 11" please.



Give Assurance of Efficiency
Where Efficiency is Needed Most

These doors, bearing the "Seal of Satisfaction," strong, tough, durable, made to withstand the hard, every-day usage of heavy service—place the responsibility for their efficiency upon their HARDWARE.

For it is the superiority and difference in HARDWARE that makes the REAL DIFFERENCE in doors.

The patented features of Jamison Hardware are the "Strong Points" of Jamison Doors.

THE ADJUSTABLE SPRING HINGES are massive. Their springs can be adjusted from time to time, whenever necessary by a simple screw adjustment that draws the door tight against the seals of contact to make it as leak-proof as when new.

THE SELF-TIGHTENING FASTENERS are heavy, strong, durable—and yet easy to operate. They prevent the door from opening unintentionally. Banged shut they make the door "stay put." The harder the slam, the tighter it stays. Regardless of how hard the door is slammed shut, there is no rebound or opening through compression.

It is difficult to tell of these important "Strong Points" in limited space. Yet, they give REAL DOOR EFFICIENCY, keeping down to a minimum, change in temperature due to leakage through heat transmission. And therein lies your profits.

When considering enlarging your storage space, it will pay you to give strong consideration to the selection of your doors. Learn all you can about them. Visit your neighbor's plants. They are invariably equipped with Jamison Doors.

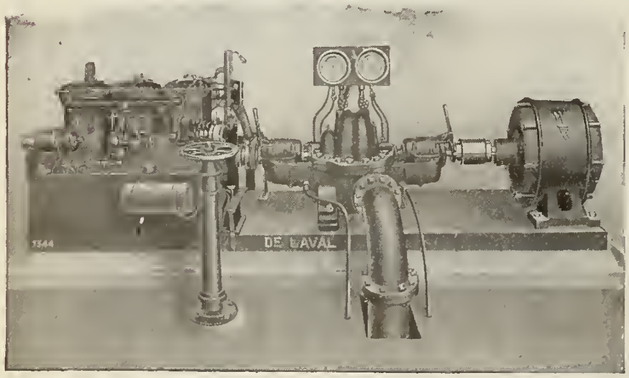
DUPLICATE POWER SUPPLY FOR PUMPING



THE De Laval centrifugal pump shown herewith was built for the City of Lindsay, Ont., and is arranged to be driven either by an induction motor, or, when electrical power is not available, by a 6-cylinder gasoline engine. A clutch is provided for disconnecting the engine when not in use. The unit is rated at 1,325 gal. per min. at 1,450 r.p.m. With a duplicate power supply there is practically complete assurance of being able to deliver water at all times. The characteristics of the De Laval centrifugal pumps are ideal for such service, as there is practically zero starting torque, and, due to the power-limiting characteristic, the De Laval pump cannot possibly overload the motor.

Flue gases can be reduced 50 degrees by careful firing and clean boiler surfaces

Such is the substantial saving that can be effected by recording and measuring your flue gas temperature with

TRADE MARK
BRISTOL'S
REG. U.S. PAT. OFFICE.
Recording Pyrometers

Of course, the temperature of outgoing gases can be decreased by economizers, or by a change in the baffling — but such changes are costly and the economy depends upon the cost of coal.

The information supplied by Bristol's Pyrometers, as to the temperature of uptake gases leaving the boilers, is of prime importance as an aid to super-efficient plant operation.

Hundreds of Bristol's Pyrometers are recording flue gas temperatures in prominent power plants. Let us tell you more about what they could do in your plant. Our new Catalog O-1401 is waiting for your address.

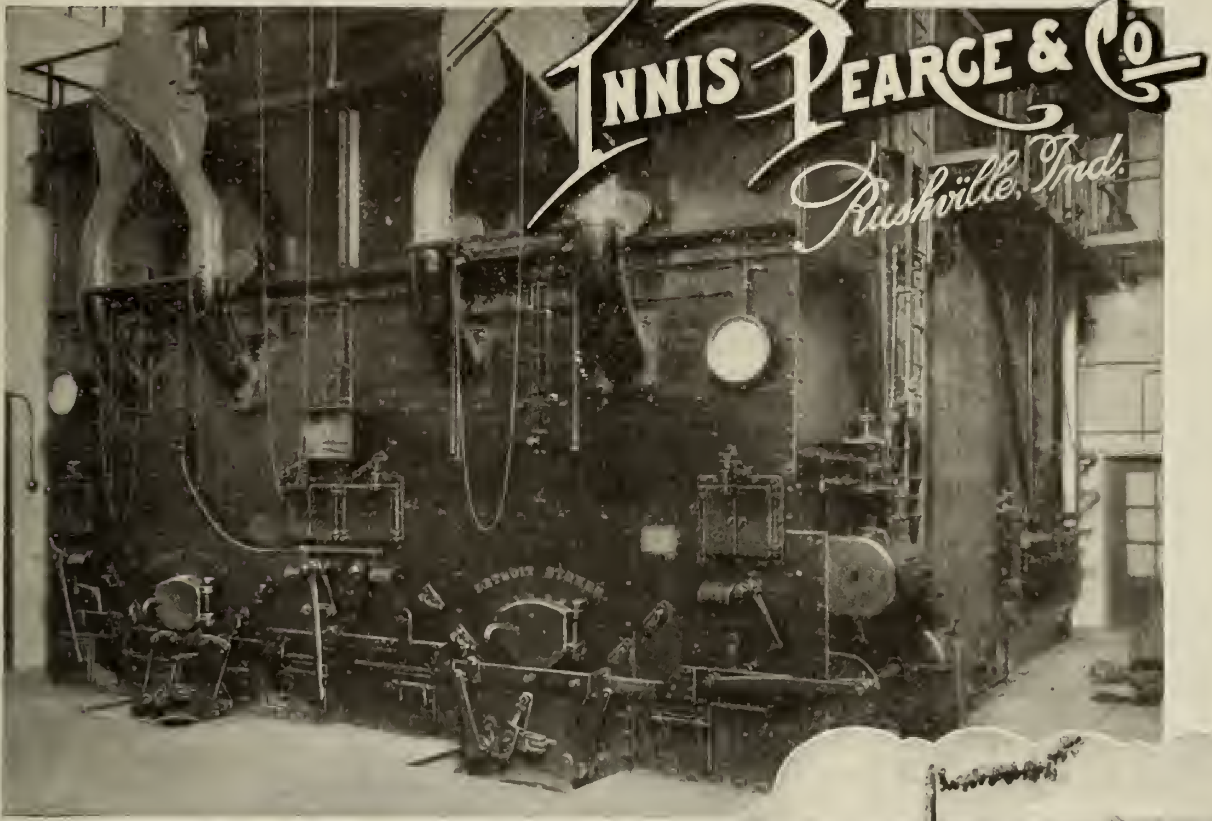
Detroit V-Type Stokers

Save daily 5 Tons of Coal

and one man's labor for



This well known furniture manufacturing company burns large quantities of wood refuse on its Detroit natural draft stokers. These stokers are particularly adapted to burning hogged fuel, shavings, and refuse, when installed with flat suspended arches.

Mr. W. H. PEARCE writes:

"The refuse which goes into our boilers is blown from the wood hog into the separator on the top of the boiler-room and the dust then freed and the shavings gravitate into the furnace. In order to utilize the full value of this type fuel, the flat suspended arch has been used instead of the crown arch, thus giving much more combustion space.

"We are burning Eastern Kentucky coal with complete satisfaction, the grates being free from any clinkers, despite the large quantities of wood refuse. The Detroit Stoker installation is very satisfactory and efficient. Our new stoker equipment is saving 5 tons of coal each 24 hours besides the labor of one man."

Savings such as these can be effected in your plant. Remember that besides natural draft stokers we manufacture Detroit Underfeed Stokers, single retort for small and medium size boilers, and multiple retort for large boilers.

A Sure Way To Conserve Pressure

Assume you have a job requiring a certain amount of low pressure exactly so much and no more—

That if the low pressure requirement is interrupted you want the delivery of all low pressure to cease until the requirement is renewed.

When you can give a mechanical device a job like that to do, and go away and know that it will be done more dependably and accurately than if you had a man stationed right there to attend to it—

We claim it is an unusual regulator.

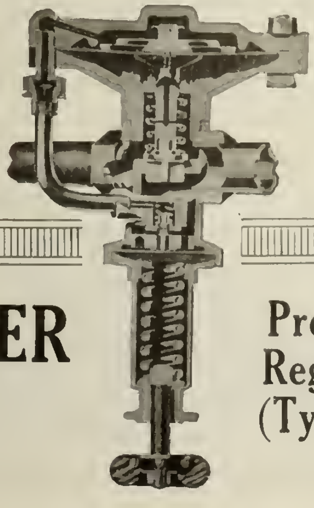
That's what FISHER Pressure Regulator, Type 90, is doing in thousands of plants all over the world.

For automatic control and conservation of reduced pressure, its equal doesn't exist.

We have a book, "Power Plant Specialties", which gives full information about this wonderful regulator and other FISHER Power Plant Specialties. May we send it to you? A card will do the trick.

THE FISHER GOVERNOR COMPANY

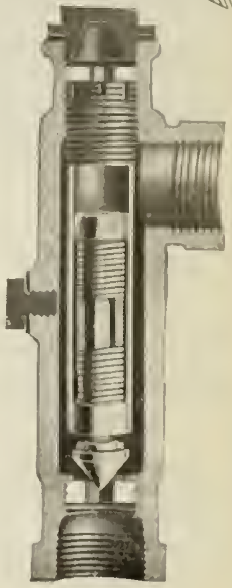
949 Fisher Avenue Marshalltown, Iowa



FISHER **Pressure Regulator (Type 90)**

For greater Steam Trap efficiency I resolve to install the Steam Trap Sarco as soon as possible

Make that "Sarco Resolution" NOW!



If a resolution is good on January 1st, why isn't it just as good or *better* NOW?

Resolve *to-day* to put the Steam Trap Sarco into your plant in place of the obsolete, wasteful traps you are now using, and start saving money, time, lost motion and wasted energy *at Once*.

Hundreds of thousands of Sarco Steam Traps are in use, demonstrating daily their efficiency in large and small plants of every type. Wherever a Sarco takes the place of an ordinary bucket or float type trap its efficiency speedily becomes apparent.

Built with but a single movable unit, its operation is the very acme of simplicity. Sarco maintenance is practically nothing, as there are no fussy parts to get out of order. And it costs only one-third as much as a bucket or float trap.

Every argument for economy and certainty of operation calls upon you to make that "Sarco Resolution" *now*.

Write to-day for Booklet J-44 and details of our 30-Day Free Trial Offer.

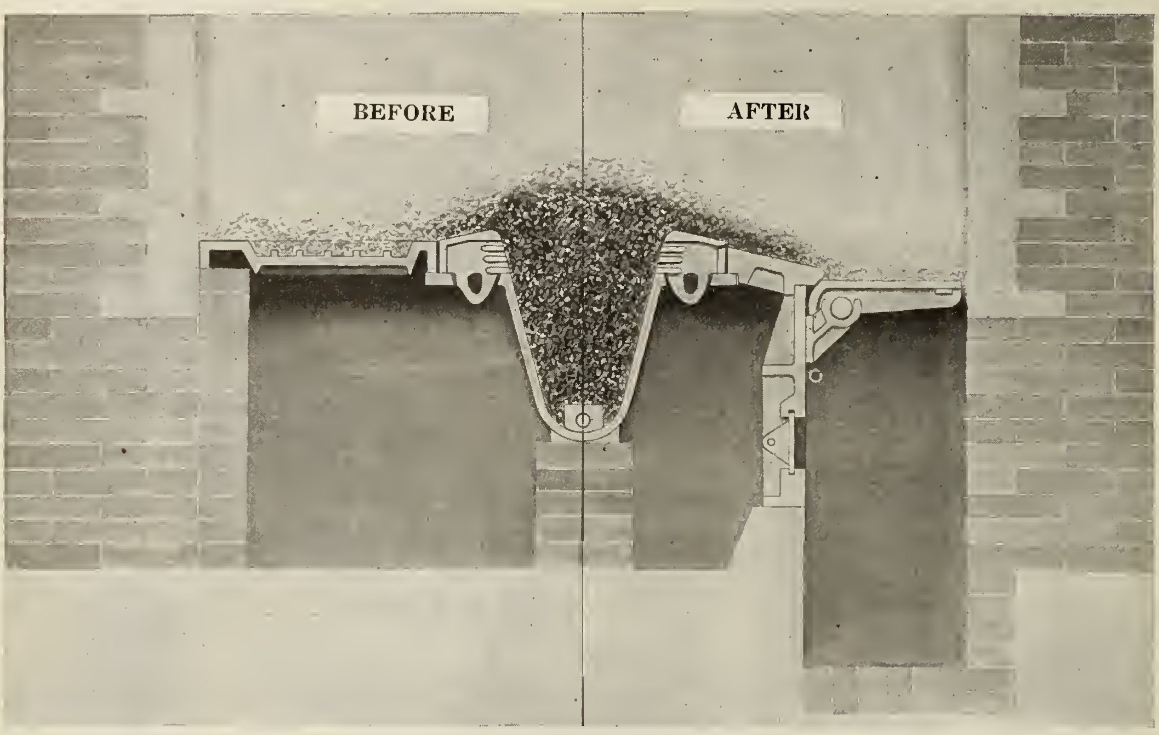
STEAM TRAP SARCO



The Coupon brings the cost of the change

See how easy the change is—just substitute the dump plates for the dead plates.

Make a side-dump stoker of your "Jones Standard"–cheap!

ANY user of "Jones Standard" Stokers can, by adding the side dump attachments, convert his hand cleaned stokers into self-cleaning side dump stokers.

As shown in the illustration above, the change is a simple one. In place of the hand cleaned dead plates (left) sloping combustion grates and hand operated dump plates (right) are used. All of the features which have won fame for the "Standard" Stoker—simplicity, rugged construction, low maintenance, high efficiency and great capacity, to mention only a few—are retained.

The cost of the change is very low. No expensive ash pit construction is needed; an excavation of only a few inches is necessary.

Here is an opportunity for every "Jones Standard" Stoker user to get an ultra-modern side cleaning stoker for practically nothing. Don't pass it up. Send the coupon opposite to the Under-Feed Stoker Co., of Canada, Limited, 146 King Street, Toronto, for the cost of converting your hand cleaned stokers into self cleaning ones.

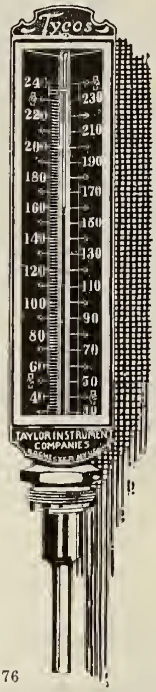
Tycos and the Boiler House



Tycos Indicating, Recording and Controlling Temperature Instruments enable the operator to figure out how much his power is costing as well as increase the efficiency of his plant. The points in the boiler house where *Tycos* Temperature Instruments can be applied effectively are

Atmospheric Relief Valve,
Barometric Pressure,
Blow-Off Lines,
Boiler Room Temperature,
Calorimeter Test,
Condensers,
Drafts,
Economizers,
Feedwater Pressure,
Flue Gas Temperatures
Furnace Fires,
Heating Systems,
Hot Water Tanks,
Humidity of Boiler Room,
Outside Temperature,
Recording Boiler Pressure Gauges,
Saturated Steam Line,
Superheated Steam Lines,
The Coal Pile.

Send for Power Plant Catalog Number One.

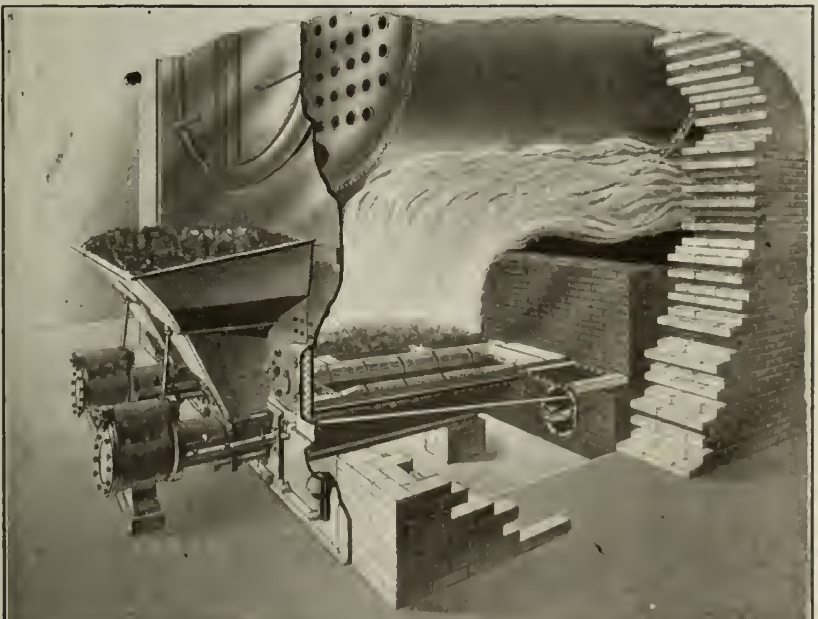
MACLEAN STOKERS



"The Coal it Saves Soon Pays its Cost"

There are many reasons why your next stoker should be a MACLEAN. Look over the following features—you know best what they would mean in your plant.

Coal Consumption is **greatly reduced.**
Cost of Upkeep is **materially lessened.**
No Special Brick is **required.**
No siftings of unburned coal.
A Smokeless Chimney is maintained.
Cleaner Tubes and heating surfaces due to the complete combustion.
Steaming Capacity of the boilers is increased.
Easy to Install and Operate.
A Constant Steam Pressure is carried, regardless of varying loads.
Responds Immediately to sudden demands for steam.

Let us estimate the saving to be made in your plant

Slaves of the Present Day

ANCIENT Greek civilization, we are told, was sustained by the servile Helots, each family having on an average five of these slaves who supplied a great part of the Greek energy. The Canadian family of 1923 has at its service 150 slaves in the form of electrical, mechanical and hydraulic energy harnessed to carry on the production of the necessities of our mode of living.

Prevalent methods of utilizing our power producing plants are far from perfect; the smaller plant or locomotive makes use of only twenty per cent. of the energy consumed, while in the more perfect installations equipped with modern fuel saving and steam generating equipment, not more than probably sixty per cent. of the energy delivered, is utilized.

To-day, every Canadian worker has, on an average, nearly two horse power available to aid his production, or almost twice as much as his brother worker in Great Britain.

The manufacture of power is the fundamental industry upon which the whole economic structure of civilization depends. The problems relating to more economical power production are paramount in importance to any other single industrial problem, for the product energy is a basic commodity indispensable to the existence of modern society.

The history of the progress of mankind from the Promethean fire and arts of Hephaestos, down to the mechanical stokers and superheaters of modern industry, is simply the story of the development of power and its application to man's use.

* * * *

Setting Air In Motion

AN OLD theory of ventilation was founded on the belief that decidedly harmful substances were present in respired air and as a result the removal of such air and its replacement with fresh air was practically the only factor considered worthy of discussion.

Foul air was considered as air that had been contaminated by human respiration and fresh air its antithesis, provided always it was obtained from out of doors and not from any place inside a building.

These terms, unfortunately, still encumber much of the literature of "aerology" and prevent to a great extent, the proper appreciation of what ventilation means at the present time and what really can be accomplished by properly designed mechanical equipment.

Leonard Hill, in his report of the recent experiments in the Physiological Laboratory of the London Hospital Medical College, says:

"Heat stagnation is the one and only cause of the discomfort arising from the so-called vitiated atmosphere of crowded rooms. The moisture, stillness and warmth of the atmosphere are responsible for all the factors and all the efforts of the engineer should, therefore, be directed toward cooling the air in crowded places by setting the air in motion by fans."

It is, therefore, apparent that the physical condition of the air is of great importance, indeed it is the determining factor so far as physical comfort is concerned. At the same time the engineer cannot safely neglect the dust content of the air, the bacteria it may contain, odors that may be present, an excessive amount of carbon dioxide, a deficient supply of oxygen or the presence of deleterious gasses.

In solving ventilation problems, each must be given its proper weight as a part of the whole.

* * * *

The Power of Example

IF I WERE in charge of a power plant I would clip every fuel saving idea published in Power House, and I would post each clipping where everybody could read it and it would confront me every time I entered the boiler room.

That's what I'd do, for in these days of high operating costs you can't afford to cease trying to reduce fuel bills.

You know the power of an example before the eyes. If you don't, let me tell a little story. It goes like this:

A man tied a donkey's head to a thistle. After a while the donkey ate it.

"I'm surprised," said the man, "that a donkey would eat a thistle."

"Why be surprised?" said a friend. "With the thistle before his eyes—with nothing else in sight—why the donkey would be an ass if he hadn't eaten it."

And there is the moral of keeping fuel saving facts before your foremen. To see—to know—how much others are saving, encourages men to save more!

* * * *

If In Doubt Ask

WHEN in doubt, ask. And that is what Canadian engineers are doing. It is what we want them to do. Power House tries to be more than a newspaper. It is a clearing house—a service station. Every month dozens of questions are answered by mail; dozens of things are done to help engineers.

Tell me the correct way to line up a Corliss engine. Will potato water keep boilers from forming scale? If the compression chamber of a gas engine is made smaller, will it give more power? How can I obtain a third class certificate? Will you send me a sample copy of Power House, a friend tells me it's one real bet?

Those are a few of dozens of questions answered this month. Send in your questions. Arthur Murphy doesn't know everything. No, indeed—not by a long shot. But he has lines that reach out to advisors and counselors. And these advisors and counselors, taken all together, know about everything that's worth knowing in the poper plant. field.

High Vacuum a Big Aid to Maximum Efficiency

By F. JOHNSTONE TAYLOR*

Modern Methods of Removing Air and Water from Condensers—Reasons for Extraction of Incondensible Vapors—General Description of Ejector Systems

IT IS now a well established fact that in conjunction with modern steam turbines it is necessary to expand the steam down to the very lowest pressure in order to maintain the maximum efficiency.

Under conditions of very high vacuum the volume of air to be dealt with becomes so great that the single reciprocating air pump, dealing with both air and condensate, becomes impracticable and other methods have to be resorted to.

The idea of dealing separately with the air and condensate originated with Sir Chas. Parsons in the shape of the vacuum agumenter, in which a steam jet was employed to extract the air at a point just above the bottom of the condenser. This may be regarded as the forerunner of a number of systems now in vogue for extracting air and other incondensible vapors from the condenser.

These in the main involve some form of ejector, which, while extremely simple in action, yet call for considerable skill in design to suit the particular conditions under which they are required to operate.

Ejectors in General

The action of the steam ejector is well known, that is to say, a jet of steam issuing at high velocity, from a nozzle placed axially in a pipe, will draw air through that pipe and this application of the ejector for maintaining a vacuum is quite a common one. In the case of condenser work however, the problem is not by any means so simple as it might at first appear to be.

With the single steam jet air ejector there is the difficulty of dealing with the air after it is extracted from the condenser, particularly when it is desired that it shall not mix with the condensate again.

Owing to risk of corrosion it is now regarded as bad practice to return the air to the condensate after it has been extracted from the condenser, in consequence it is necessary to raise its pressure slightly above that of the atmosphere before it can be conveniently discharged.

The single steam jet ejector cannot effect this efficiently, hence the adoption of a two stage ejector and in some instances a three stage one, both of which are. as will be shown, often combined with an intermediate condenser.

Thus a further development of the Parsons vacuum augmenter is seen in the two stage ejector in which steam is used for the first stage and either steam or water for the second, the three stage system merely carrying the process a step further.

In all these arrangements the condensate is dealt with by a separate pump of the centrifugal type.

Two Stage Ejector

Fig. 1 shows a modern type, consisting of two ejectors working in series.

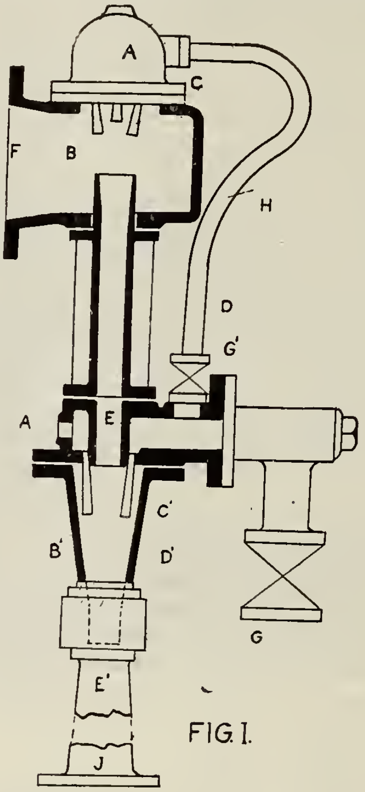

FIG. 1.

There are two compression stages each of which is under the control of a group of steam nozzles operating in series.

Each stage consists of a steam chest as shown at A and A,, air suction chambers at B and B^1, a group of convergent nozzles at C and C,, convergent and divergent compression pipes at D and D^1 terminating in diffusion pipes E and E^1.

The inlet branch F is connected to the condenser and the steam supply pipe to main inlet G on the second stage steam chest while branch H, fitted with a stop valve G, conveys a supply of steam to the first stage nozzles.

The first stage group of nozzles, c, give the initial motion to the air and gasses which are partially compressed in the first stage ejector, while in flowing through the second stage they attain considerable velocity, the final velocity being imparted by the second group of nozzles C^1—C^1.

On passing through the second stage compression pipe D^1 the mixture enters diffuser pipe E^1 wherein the kinetic energy is converted into useful work in overcoming the atmospheric discharge pressure at the discharge end J.

This type of ejector may be taken as typical of the simpler forms and by slight alteration in the general construction it may be combined with an intermediate condenser between the stages, an arrangement which as will be shown, has several advantages.

Development of Ejector

One of the great defects of the earlier forms of ejector air pumps was their very high steam consumption which rendered the production of high vacuum costly. The efficiency of a steam operated ejector depends to a large extent upon the amount of friction surface which can be provided between the air and the steam. A large steam nozzle is capable of passing a large weight of steam but it is only the outer surface of the jet which is available for producing vacuum.

Hence the adoption of several small nozzles in place of one large one while the distance between nozzles and diffuser throat is made as great as possible.

These improvements considerably reduced steam consumption but there still remained other troubles, the principal of which was instability. This is liable to occur at high vacuum with varying load conditions and is due either to the steam jets not filling the diffuser throat or to their being choked in the throat.

Various methods have been adopted to overcome this trouble amongst which may be mentioned the stabilizing valve, the annular diffuser, and the water jacketed nozzle.

Water Jet Ejectors

Water jet air ejectors are principally used in conjunction with the kinetic system. A water jet ejector of orthodox design is shown in Fig. 2. It consists essentially of four stationary parts.

Nozzle box A is a cast iron chamber with branch B for the air pipe from the condenser. A nozzle C of bronze extends downwards from the top of the box to within a short distance above the bottom flange while the water supply pipe is bolted to the top of the nozzle box, the purpose of the nozzle being to convert the pressure of the water into velocity.

---

*Specially written and illustrated for Power House.

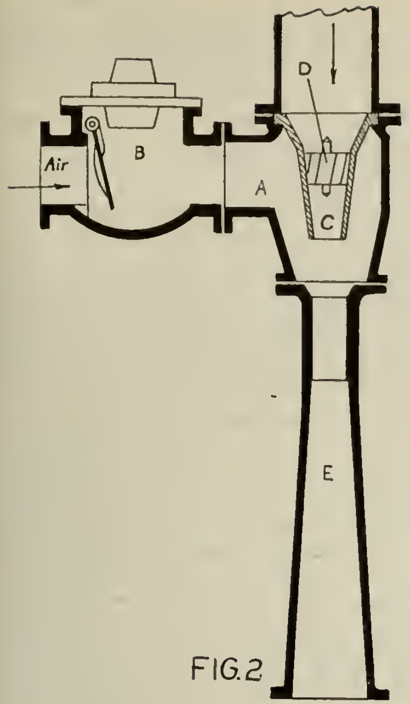

FIG.2

Inside the nozzle is cone part D, having vanes arranged on an angle. These give a rotary motion to the water and at the same time break up the surface of the cone of the water, thus ensuring its being able to entrain the air with maximum efficiency. The water discharges into diffuser E bolted to the bottom of the nozzle box.

In the diffuser the entrained air is compressed from the vacuum pressure to atmospheric pressure, the compression being carried out isothermally.

After the water has been passed through the air ejector it can be returned to the suction culvert, where, owing to the fact that the pump suctions are not very near the ejector discharge, the air separates out.

When cooling towers are in use this water for the ejector may be shunted off the circulating system, but if the water is led to the circulating pump through a closed pipe it is necessary to provide an air separator between the air ejector discharge and the pump suction.

An Air Separator

This air separator, shown in Fig. 3, consists of a conical vessel in which the water entering at the small end is reduced in velocity as it travels towards the large end.

With the velocity falling to about 1 ft. per second the air is separated from the water and is discharged through a vent pipe, A, at the top, while the water returns to the main circulating pipe suction. Should the water levels involve either pressure or vacuum in the separator, float control valves are fitted.

As the air becomes separated from the water it accumulates in the top of the vessel and gradually depresses the water level, thus lowering the float, B, and slightly opening the air valves, A, at the top so as to allow the air to escape.

Conversely if there is a tendency for the pump to draw the water out at a greater rate than that at which it enters the separator, the float, continuing to fall closes the water outlet valve, C, at the bottom.

Kinetic System

The value of the kinetic system lies in the greatly increased capacity of the water jet by first withdrawing the air and compressing it by a steam jet followed by a system of water jets.

The latter, moving at a high velocity, have been in use for many years for the production of vacuum, but a water jet has a relatively low capacity of assimilating and withdrawing air, and if the amount of air to be removed is large, the quantity of water or the pressure necessary for the jet becomes considerable and excessive power is expended in the process. If, however, the air to be extracted is previously compressed by the use of a steam jet ejector then the air withdrawing capacity of the water jet device is considerably increased.

In the case of a kinetic plant the steam is introduced into the air suction pipe through a high velocity nozzle which thus entrains the air and mixes intimately with it. The steam is condensed on the secondary sprays of the water jets and the resultant liquid carrying with it all entrained air and gases is ejected by the main water jet to the kinetic tank, from which the air and gases escape to the atmosphere. Either live steam or exhaust steam (if available at a pressure of over 10 lbs.) may be used, the quantity varying from ½ to ¾ per cent. of the steam condensed according to the size of the installation. The water for the kinetic jet is condensate already removed.

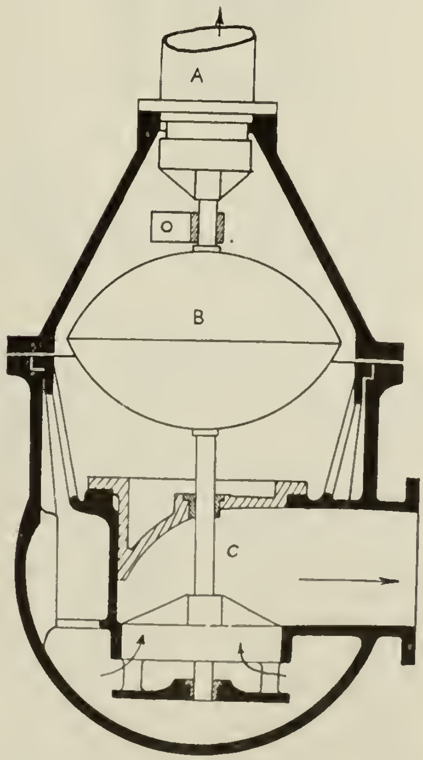

FIG 3

The whole of the latent heat contained in the steam used in the steam nozzle is absorbed by this water, which in consequence reaches the feed tank at a higher temperature than when it left the condenser. The condensate is withdrawn from the condenser and discharged into the kinetic tank by a centrifugal extraction pump. The general layout of a system of this kind is shown in Fig. 4.

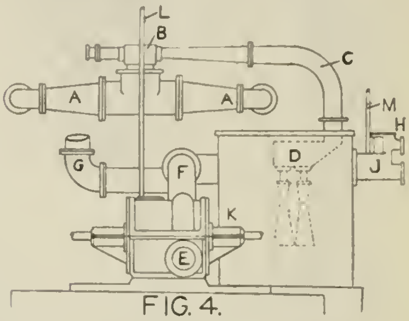

FIG. 4.

Referring to the lettering on the diagram, A is the air suction pipe, B the steam jet, C the air pipe to kinetic ejector, and D the kinetic ejector itself.

The kinetic pump suction pipe is shown at E, and the discharge pipe at F, while G is the condensed water pipe to the extraction pump and H the feed water delivery pipe. At J is a float controlled delivery valve, K is the kinetic tank, L a vent pipe and M the bypass from tank to condenser.

The exponents of the kinetic steam and water jet system claim that it is much more economical than systems employing high pressure steam jets in series and that it is the most efficient air pump extant, because practically the whole of the energy expended reappears in the form of heat in the kinetic tank whence it is returned to the boilers subject only to a small loss through radiation.

Withdrawal of Air

Reverting to Fig. 4 withdrawal of air from the condenser is effected by a steam jet, B, followed by the action of kinetic ejector, D, supplied with water by kinetic pump through pipe F, and discharged into kinetic tank K. Condensate water flows through pipe G into the extraction pump which discharges into the suction of the kinetic pump through a non-return valve in the pump casing.

The excess of water in the tank corresponding to the feed water is delivered by the kinetic air pump by means of pipe H and float controlled valve J, into the feed tank which may be placed overhead.

The Intermediate System

It was before stated that the introduction of a subsidiary condenser between the stages of a two stage ejector had been found of considerable advantage. By the introduction of this small "Intercondenser" between the

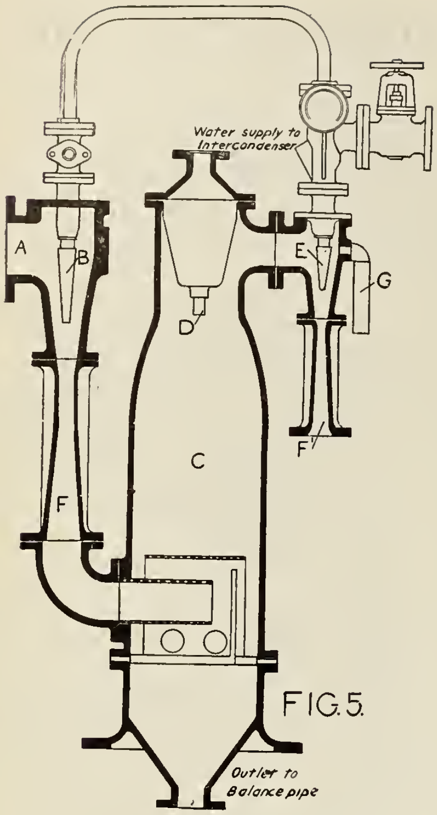

FIG. 5.

stages the work to be performed by the second stage is very largely reduced enabling the same results as regards weight of air extracted to be achieved with practically half the steam.

The intercondenser system permits of complete condensation of the steam and separation of air from the condensate while maintaining a high rate of heat transmission, and the second stage compression is thus carried out under the most favorable conditions. The operation of an ejector air pump with an intercondenser is precisely the same as that of one without, while the intercondenser may be either of the surface or jet type, according to individual design.

Two Stage Ejector

An air pump of this class is shown in Fig. 5. Air is drawn in from the condenser at A compressed by steam jet, B, the steam-air mixture being discharged into the intercondenser, C, where the air is cooled and the steam condensed by water jets from D. The air is withdrawn from the intercondenser and discharged to atmosphere or feed heater by second stage jet E. The water used in the intercondenser is condensate from the main condenser and it is drained away by passing it back to the extraction pump suction by means of a pipe termed a balance pipe. This pipe in addition to draining the intercondenser provides and maintains the balance of pressure between the latter and the main condenser.

Stability Essential

Reference has already been made to instability under varying load, and in this connection stabilizing valve G should be noted.

It must be remembered that the density of the mixture discharged through the throats of the combining tubes will vary according to the steam condensed and to such an extent that the required compression cannot at times be effected. This is very important especially as regards the second steam jet, inasmuch as atmospheric air will rush in to the auxiliary condenser until the required density of the mixture is established when the second jet again begins to discharge.

Stabilizing valve G is fitted to guard against this. It is simply an automatic air inlet valve to the suction pipe from the auxiliary condenser. By setting this valve to admit air at a suitable vacuum in the auxiliary condenser the density of the mixture handled by the second jet is prevented from becoming too low thus ensuring the stability of the whole apparatus.

Nearly the whole of the heat of evaporation of the steam used in the jets is recoverable, that from the first jet being added to the condensate withdrawn from the main condenser. The heat from the second jet is usually absorbed by a feed heater, the condensate from the main condenser providing the condensing medium.

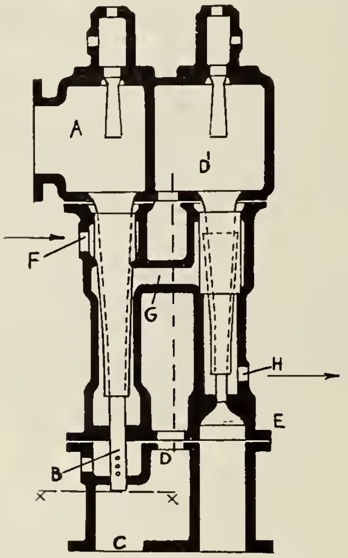

FIG. 6.

Water Jacketed Jets

The system of admitting a supplementary supply of air through a stabilizing valve is not regarded with favor by all designers, some of whom claim that not only is the method incomplete owing to the inflow of air being intermittent but that the re-compressing of the stabilizing air requires additional work and reduces the efficiency.

The arrangement shown in Fig. 6 originated on the assumption that it is necessary to keep the convergent nozzle cool by the introduction of a water jacket, which may be regarded as the essential feature of the system.

Fig. 6 shows a two stage ejector arranged to work with an intercondenser. Air from the condenser enters at A and is compressed for the first time as far as X—X. A jet of injection water enters holes B, and condenses the steam in the first stage, while the injection water and condensed steam flow away through C, returning to the condenser through a U tube.

The incondensible gases freed from the steam follow the line D—D^1 and are compressed a second time as far as E whence with the steam of the second stage they are discharged to the atmosphere, usually through a feed water heater in which the steam is condensed, the heat being absorbed by the feed water. The circulating water enters at F, passes along G and out at H.

The Annular Diffuser

The annular diffuser is another arrangement introduced with a view to getting over the trouble of instability. By this means the entrainment surface is considerably increased for a given weight of steam per second, while the length of the jet can be kept within reasonable proportions. Thus internal losses due to eddying are eliminated and the penetrative effect of the jet in the diffuser is increased. At the same time the areas of all the passage ways can be made large enough to ensure absolute freedom from choking.

It is a well known fact that in the ordinary type of ejector apparatus, the dimensions of the various parts require to be extremely accurate to secure economical working, and further, these

(Continued on page 39)

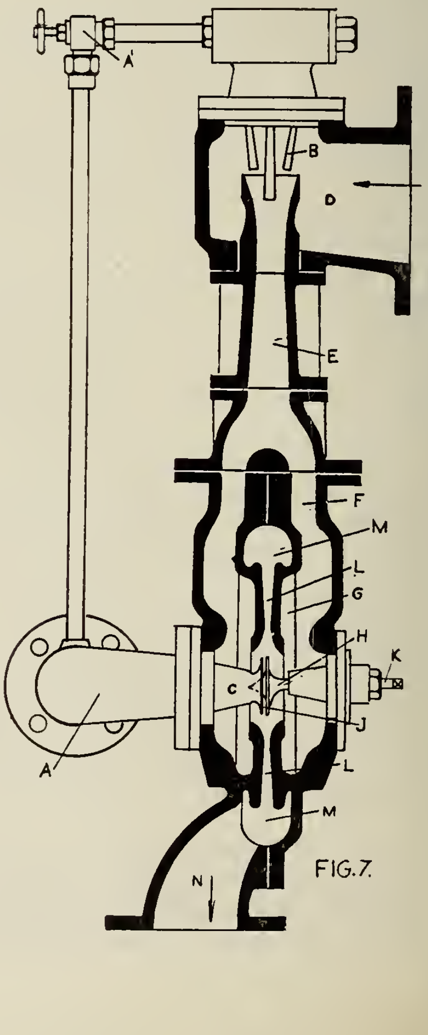

FIG. 7.

Demonstrating Vacuum Heating System Savings

Tests in Building Containing 6,400 sq. ft. of Direct Radiation, or its Equivalent, Show Saving of 345,000 lbs. of Steam in Seven Months

IN A recent report of the Heat Utilization Committee of the National District Heating Association, a section is included on vacuum heating, by J. E. Seiter, in which the results of two interesting tests are presented to demonstrate the savings possible in large buildings with the use of a vacuum in the steam heating system.

Both tests were run in office buildings, in a city, where mild weather with outside temperatures between 40 deg. and 70 deg. Fahr. constitutes about 50 per cent. of each heating season; moderately cold weather, with outside temperatures between 20 deg. and 40 deg. Fahr., and only 5 per cent. can be classed as "severely cold."

To determine the saving, if any, of operating under a vacuum, the first test was run in a four-story brick building, containing 200,000 cu. ft. of space. The heating system was re-designed and rebuilt by an experienced heating engineer in 1916, at which time it was remodelled into an overhead-feed, thermostatically-operated, two-pipe gravity system, with thermostatic traps on all radiators.

It contains 2,170 sq. ft. of direct radiation and 700 sq. ft. of indirect radiation, making a total of 6,400 sq. ft. of equivalent direct radiation. While the system was operating as well as any system of this type, the engineer in charge of the building asked to have a vacuum pump installed.

Pump Was Installed

Last summer a pump was installed, but before the changes were completed it became necessary to use heat in the building and the ventilating equipment was not connected to the vacuum pump which therefore operated on the direct radiation only during the past winter.

The building is used by departments which have men working twenty-four hours per day. During the night the ventilating system is shut off, but the direct radiation is left on.

During the heating season the vacuum pump was run only during the day and the system was operated by gravity at night, as there was no engineer on duty during the night.

Comparison of operation of the system before and after vacuum pump was installed.

Month	Steam Consumption, lbs.		Steam Consumption, lbs. per °F. below 70°F.		Saving % by vacuum	Steam Consumption 1922-23 cor. to temp. in 1921-22
	1921-22 pressure operation	1922-23 vacuum operation	1921-22 pressure operation	1922-23 vacuum operation		
Oct.	361,595	231,200	2055	1445	23.4	250,000
Nov.	477,295	410,796	1535	1520	1.0	472,500
Dec.	572,650	532,966	1455	1300	11.9	512,000
Jan.	724,750	704,076	1570	1636	loss	756,000
Feb.	585,845	588,500	1410	1300	7.8	543,000
Mar.	555,685	524,000	1678	1345	19.8	446,000
Apr.	360,885	457,173	1650	1450	12.1	318,000

Total consumption from October 1 to May 1, 1921-22, lbs.	3,642,505
Total consumption from October 1 to May 1, 1922-23, corrected to temperatures for 1921-22, lbs.	3,297,500
Saving in seven months by using vacuum pump, lbs.	345,000
Average saving per month, lbs.	50,000
Estimated total saving for season by use of vacuum pump in lbs.	395,000
Estimated total savings in dollars, with steam at $1 per 1,000 lbs.	$395.00
Total actual cost of pump and piping installed	$658.00

These results are self-explanatory and the savings are evident. During January a loss is shown which can only be accounted for by the fact that in January, the pressures were varied for test purposes. These tests consisted of running at a pressure for one week and a vacuum for one week. During the latter part of January the system was operated at about 3 lbs. pressure. It may be that operating under these pressures offset any saving which might have been effected. For this reason, the saving during February is also low.

The results by operating under pressure one week and vacuum the next are shown in Fig. 1. The points plotted indicate data obtained on days with the outside temperatures ranging from 25-35 deg. Fahr. It was not possible with these outside temperatures to increase the vacuum much above 5 in. and still heat the building. The system is thermostatically operated and theoretically no saving should be shown, but actually it is very marked.

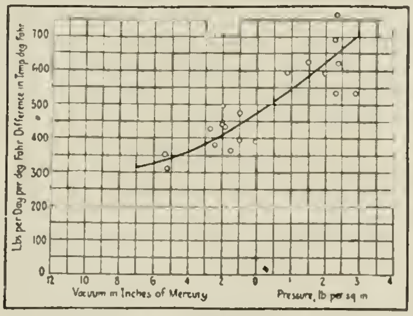

Fig. 1—Operating Results in a 4-Story Building.

Tests were then run in a ten-story brick building, containing 40,000 sq. ft. of radiation, the system installed being an overhead feed, vacuum system, having all returns above the vacuum pump. The thermostatic equipment in the large rooms is of the so-called positive type in which the radiator valve is either wide open or tightly shut. In the smaller private offices the thermostats operate modulating valves permitting the radiators to heat fractionally.

The results of these tests are shown in Fig. 2. The points shown are for tests of eight hours each, during which the pressures were kept constant. The curve drawn through these points was obtained by calculating the steam consumption for various steam temperatures and a 70 deg. Fahr. room temperature.

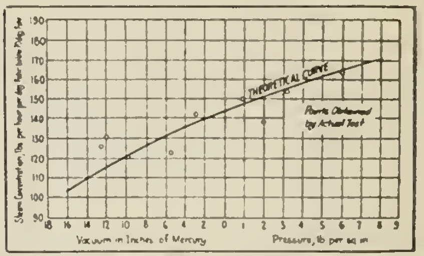

Fig. 2—Operating Results in a 10-Story Building.

Later in the season the test was repeated to check these results by operating for longer periods than eight hours. This was a difficult task, due to the wide variation in the outside temperature, and because of the difficulty in holding a constant pressure over extended periods. When complaints became too numerous, that the building was not comfortable, (usually too hot), the test had to be discontinued until more favorable conditions presented themselves. For this reason there are no points between 1 lb. pressure and 4 in. of vacuum. All the results are plotted in Fig. 3.

The points obtained are averages for periods of about five days each. The curve drawn through them was obtained in the same manner as in the previous test.

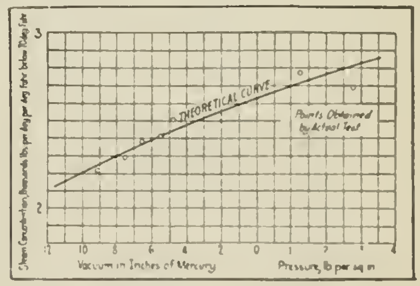

Fig. 3—Results of Second Test.

In all of these tests, the vacuum or pressure referred to was at the reducing valve and not at the pump. During all of the tests, the vacuum at the pump was maintained so as to give between 4 in. and 7 in. of mercury pressure drop through the system, that is from the reducing valve to the pump.

During the test, the pressures were watched throughout the building. At the time steam was turned on the building in the morning, there was a 3-in. pressure drop between the pent house and the risers at a point on the 6th floor. This drop was 2 in. through the remainder of the day.

The drop in pressure between the trap discharge of a radiator on the sixth floor and the pump was 5 in. when the steam was first turned on. During the balance of the day, this dropped to 2 in.

All the pressures were for a day of 26 deg. Fahr. outside diameter. They vary for other temperatures, being less in mild weather and greater in cold weather.

The pressure drop through the thermostatic traps on radiators equipped with the positive type of thermostatic control, varies with the reducing valve setting and the pump vacuum, acting as a sort of shock absorber and taking up any excess pressure which may exist. This drop can be kept as low as required by watching the circulation in the building.

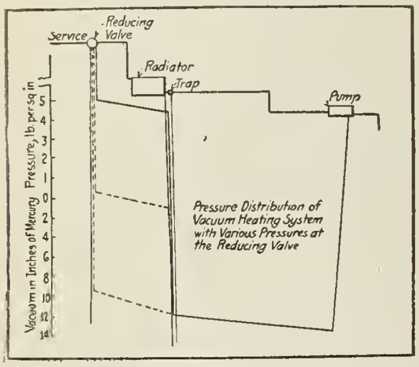

Fig. 4—Pressure Drop Through System.

This pressure drop through the system is diagrammatically shown in Fig. 4. It will be noted that the pressure drop from the reducing valve to the radiator and from radiator trap discharge to the vacuum pump remains practically constant, for any reducing valve setting varying with the density of the steam while the pressure drop across radiator trap varies with the reducing valve setting.

Where the radiators are equipped with modulating valves the excess pressure in the system is taken in these valves instead of the traps.

The occupants of the building do not like pressure above atmospheric on the radiators. The radiant heat is too great and the thermostats do not maintain uniform temperatures.

Extremely high vacuums work very well where there is piping large enough to supply sufficient steam to all radiators.

Previous discussion of vacuum heating by the committee brought out the objection of vacuum heating due to the pressure drop across the radiator trap, causing them to permit vapor to enter the return lines. This condition was carefully watched; no appreciable amount of vapor was noticed passing through the traps at high vacuums. The drop across the trap can be as low as required approaching that of an atmospheric system. No cold water jets were used or were necessary to maintain a high vacuum. No vapor was ever noticed around the meter. An economizer was used for heating domestic water but was on the discharge side of the meter. Steam used for heating water was not considered in the test.

Tests Heating Value of Lignite Char

Ottawa Believes Carbonizing Oven May be Invaluable Should Anthracite Supply Fail

CONSTRUCTION of an oven that turns lignite into a substance with similar heating properties to anthracite has resulted from experiments conducted by the U. S. Department of the Interior through the Bureau of Mines.

An appropriation of $100,000, for the purpose of investigating lignite, was made four years ago. The Bureau of Mines made the discovery in co-operation with the Canadian government, and as a result, lignite char should be available in the Northwest in any periods of hard-coal famine that may occur in the future.

One Third Lignite

Of the continent's coal resources, it is estimated that 1,057,290,000,000 tons, or nealry one-third, are lignite. The lignite of the Northwest is brown, dull, markedly woody in texture, has no coking quality, and carries a great percentage of moisture. Its disintegration on exposure is so rapid as largely to prevent its shipment any distance, except during the excessively cold northern winters, when it is, of course, frozen.

Lignite takes fire quickly from spontaneous combustion, so that its safe storage in even small quantities is exceedingly difficult. It does not "coke," in the sense that bituminous coal cokes, but rather crumbles when being carbonized, or when thrown into the fire, and thus gives rise to difficulties in firing and substantial loss, as unburned fuel, through the grate bars.

Carbonizing Oven

Experiments have been made by various agencies in the past looking toward the utilization of the northwestern lignites in carbonized or powdered form, or in the form of briquets. While all this experimental work has held some promise of success, the commercial development of these vast fields of lignite has not been worked out. An appropriation of $100,000 for an investigation by the Department of the Interior, through the Bureau of Mines, to determine the commercial practicability of producing a benefited solid fuel from lignite, was made in 1920. As a result of this experimental work, a carbonizing oven, which has every indication of being a practical, commercial oven, was designed, constructed, and operated, during the summer of 1922. Quantities of the oven's product, known as lignite char, have been tested and found to possess heating properties very similar to those of anthracite coal.

The Canadian government has expended nearly $1,000,000 in an exhaustive research looking toward the production of benefited solid fuel from lignite, but seeing the carbonization oven in operation, decided to construct a similar oven and to give it a thorough test. The tests of the oven have been highly successful, and the Canadian engineers conducting the experiments have reported to the Department of Mines at Ottawa that the oven is a practical and commercial oven, now past the experimental stage.

C. A. S. E. Notes

At the meeting of the C.A.S.E., Ottawa Lodge No. 6, on Sept. 4, 1923, the chief topic under discussion was the membership campaign suggested by the Grand President of the association, James J. Sullivan, and a committee was formed to consider ways and means of procuring new members. Ottawa Lodge No. 6 are taking over new quarters at Boileau's Hall, Booth Street, Ottawa, where the first meeting in October will be held. Plans are being made to have a "house warming" in the form of a social evening, and also to open the membership campaign.

Many engineers will be invited and will be acquainted with the aims of the C. A. S. E.

A motion of congratulation to James J. Sullivan, on his election to the grand presidency, was carried unanimously, and confidence in his efforts was expressed.

Mr. Sullivan stated that he intends to do his best to show that the confidence placed in him by the members of the association was not misplaced, and that he thoroughly realizes the honor conferred upon him. Ottawa Lodge No. 6 feel honored that one of their members was chosen as leader, and they realize that a more conscientious man, or one who would place more interest in the work of the C. A. S. E. would be hard to find. Mr. Sullivan has the united support of his entire lodge.

The meetings will be held on the first and third Thursdays of each month, and all visitors are assured of a sincere welcome at any time they care to visit the association.—FRANK DAVIS, Rec. Secy.

Boiler Room Piping for Power and Steam Pumps

Attention to Details by Stationary Engineer at Time of Installation Greatly Simplifies Repair Work in Years to Come

NOTHING so greatly aids the stationary engineers of Canadian power plants as a proper initial installation of the pumps in the boiler room.

This article is written to illustrate the connections past experience has proven most adaptable.

The vertical receiver, 2, shown in Fig. 1, receives th edischarge of hot water from several traps in a heating system through the tee 3. A tee is used here instead of an ell in order that the plug may be removed to inspect the interior of the receiver. These returns are not sufficient to supply the boiler, hence the supply is augmented by cold water under pressure through the balanced, automatic valve, 4, which is controlled by the float, 5, maintaining a nearly constant supply of water in the receiver. A vent pipe, 6, allows steam from the hot water to escape from the receiver, thereby preventing pressure from accumulating, but the cold water discharges into this pipe through a perforated pipe in the tee, and condenses the vapor, thus saving the heat.

The power pump, 7. is driven by a belt from the engine shaft. The suction pipe, 8, receives its supply from the receiver and delivers it through 9 to the boiler. As this pump must run at a constant speed, and as the supply of water must be varied to meet changing conditions, a by-pass valve, 10, is provided, hence, by opening this, a part, or all, of the water may be returned to the suction pipe.

Feeding a Battery

Fig. 2 illustrates the steam end of a pair of duplex steam pumps, used for feeding a battery of six boilers. They are located in a small pit about 10 feet deep without room enough to walk around them.

The supply is received from a horizontal tank, or, receiver, into which the condensate from a large heating system gravitates under atmospheric pressure only. The speed of these pumps is regulated by a float valve, according to the supply of water coming to the receiver. The steam is delivered to the tee, 2, to which is attached the brass oil cup, 3. This is for emergency use only, as a slight feed lubricator discharges oil into the main steam pipe. The steam is distributed in both directions by the tee, 4. Both pumps may be shut down by the globe valves, 5 and 5. Brass unions are shown at 6, 7, 8 and 9, which were provided for the following purpose:

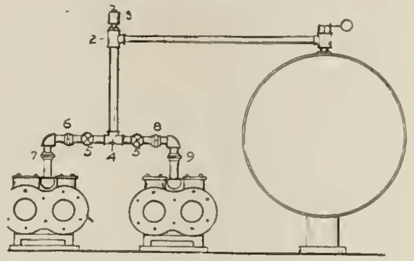

Fig. 2

The steam chests of these pumps are bolted to the tops of the cylinders in the usual way, with sheet packing in the joints. When this packing blows out it must be replaced in a short time, hence when these four unions are disconnected the steam chests can be lifted from their places (so far as these pipes are concerned), and the old packing cleaned off. When the new packing is on, the steam chests and unions are replaced.

Remove Exhaust Pipes

It is necessary, however, to remove the exhaust pipes which are connected into the exhaust chests, as shown in Fig. 3. Flange unions are shown at 2, 3, 4 and 5, and when four bolts are removed from each of them, they can be quickly removed, so that the steam chests can be lifted without touching the upper parts of the flange unions.

This plan called for considerable extra work to instal, but that was done when there was time enough for it. When this packing must be replaced, there is no time to spare.

The angle valves, 6 and 7, are necessary, because the exhaust steam goes into a heating system, hence they must be closed when the pumps are shut down. A long sweep tee is shown at 8. This causes the exhaust steam from each pump to be turned upward into the vertical pipe instead of squarely meeting the exhaust from the other pump, as it would, if a short tee was used.

Attention to such details by the engineer makes all of the difference between smooth operation and less efficient results.

Nipples in Both Ends

Fig. 4 illustrates the water ends of these pumps, also the piping for the same. The suction pipe is laid between the two water cylinders, connecting into a tee at 2. Nipples in both ends of this tee carry angle valves at 3 and 4. Water is discharged through the angle valves, 5 and 6, into the cross, 7. Thence it goes through the vertical check valve, 8, and the gate valve, 9.

An outlet nipple and valve are provided at 10 in order to discharge water to the sewer whenever it becomes necessary to do so.

When one of these pumps has been laid off for packing the pistons, it becomes filled with air, hence by opening 10, this air is disposed of in much less time than it would go through the pet cock that was on the water chest, and the water which comes with this air goes to the sewer, instead of on the floor.

The receiver which forms a part of this system deserves special attention, as it shows an opportunity for much improvement. See Fig. 5.

"Home Made" Receiver

The condensate is discharged at 2, and the suction pipe is connected at 3, hence sediment from pipes in the heating and return systems falls directly in front of the suction pipe, and some of it goes to the pumps. This is a "home made" receiver, as the body was made in a boiler

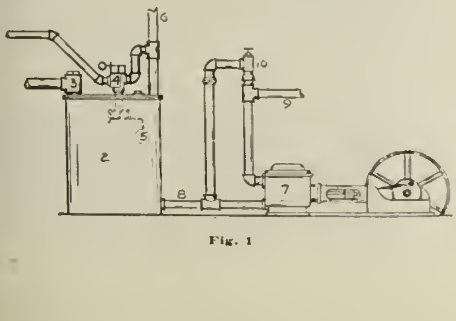

Fig. 1

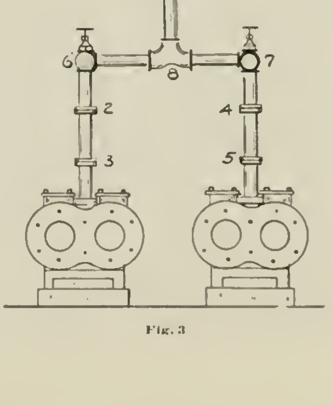

Fig. 3

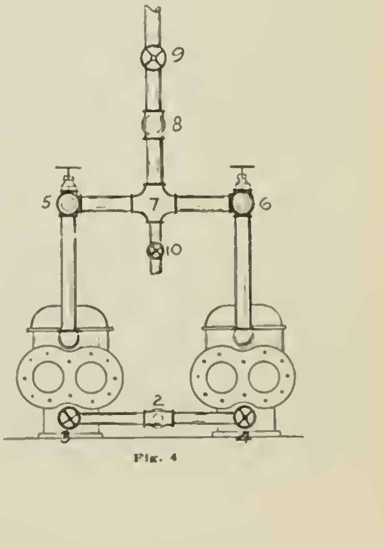

Fig. 4

shop, and the holes were bored with a ratchet drill on the job. It should have been designed with the inlet at one end, and the outlet at the other, thus allowing sediment to collect on the bottom until it could be removed through the manhole, 4.

A blow-off valve was provided at 5. but no pressure is carried on this receiver, hence the sediment could not be blown out, and it soon filled the pipe and rendered it useless until it could be taken out and cleaned. This pipe was removed and the hole plugged. A drip pipe and angle valve was installed at 6, through which the water can be drawn off from the receiver, and it carries a portion of the sediment. It has never been clogged with foreign matter so that it could not be used. The automatic balanced valve, 7, controls the speed of these pumps, according to the amount of water coming to the receiver as before mentioned.

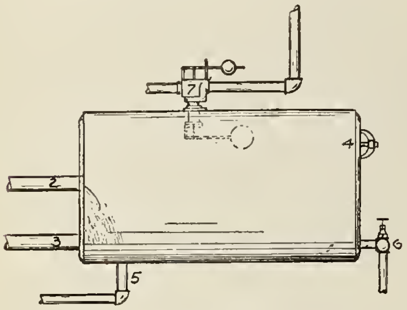

Fig. 5

Letters patent have been issued incorporating the Pemaco Oil, Limited, Moose Jaw, Sask. Capital $300,000.

The Hydro Electric Power Commission are preparing to commence work on the construction of the two new electrical power units which are to be installed at Cameron Falls, Ont.

The Minister of Public Works, Winnipeg, Man., has been receiving tenders for stokers for water tube boilers at power house, Hospital for Mental Diseases, Selkirk, Man.

The Provincial Department of Telegraphs and Telephones, Victoria, B. C., are receiving tenders for a telephone exchange building estimated to cost $10,000. Plans and specifications are with the superintendent of the department.

The consolidation of the Schaeffer & Budenberg Manufacturing Co., and American Steam Gauge & Valve Manufacturing Co., was effected a year ago. Announcement is now made that hereafter these companies will be known as American Schaeffer & Budenberg Corporation. This corporation manufactures a complete line of valves and instruments for indicating, regulating and controlling pressures, temperatures and speeds.

Watson Stands Pat on Superheat Views

Author of "Easy Lessons in Engineering" Glad to Receive Criticisms, but Insists His Objections Are Real

A LETTER of criticism has been received regarding M. Barry Watson's article on the "Use of Superheat" in the August 20th issue of Power House, and since the information given may be of interest to many readers of Power House, part of the article to which exception has been taken, follows:

"Another type of superheater consists of a number of close bent tubes, one of which is illustrated. The two ends of each bend connect to headers in the smoke box, while each bend extends into one of the fire tubes of a fire tube boiler. This type is extensively used in locomotive practice. Its chief objections are the extra resistance to the draft, and the fact that the superheaters must be removed when the tubes are to be cleaned."

The criticism reads as follows:—

"In this connection it has been our experience that it is not necessary to remove the superheaters in order to clean the large and small tubes. We are quite safe in saying, that with something like 40,000 locomotves on this continent using fire-tube superheaters, if it was necessary to remove the units in order to clean the flues, the fire-tube superheater would have been a dead issue years ago, owing to the cost and delay of such removals.

"The cleaning of large flues in which the units test is very easily carried out in the roundhouse, by a ¼ in. or ⅜ in. iron pipe connected to an air supply. All that is necessary is systematic and regular cleaning. If this is neglected, the use of a rod to punch out the accumulation of cinders, becomes necessary, but the fact that such a large number of locomotives are in regular daily service, equipped with this type of superheater, is in itself evidence that there is no need of removing the units to clean the flues.

"The same thing applies to marine practice, in which there are some thousands of fire-tube superheaters in regular service.

"As regards the effect on the draft, the diameter of the large flues, as well as that of the unit pipes, is carefully proportioned, so that there is no material effect on the draft."

Mr. Watson is not a locomotive engineer, but from his experience with fire-tube boilers as a stationary engineer, he cannot apply the above criticism to stationary practice, for with certain types of coal, especially when using natural draft and small loads, the soot and ash dust sometimes stick to the inside of the fire-tubes so tightly that no matter how often the flues may be blown through it is necessary to have them thoroughly cleaned at comparatively short intervals with some type of mechanical cleaner. This cleaning would necessitate the removal of the type of superheater mentioned.

In the case of the locomotive, it is quite likely that the trouble experienced with dirty flues in a stationary boiler is less serious on account of the very intense draft induced in a locomotive furnace at quite frequent intervals, which gives a sufficiently high velocity of the gases through the flues to carry away most of the soot and cinders which may have settled on the tube surfaces under light load conditions.

For the same reason the draft in a locomotive boiler would be much less obstructed than in a natural draft stationary boiler by the presence of this superheater because such intense draft is induced by the exhaust steam that there is always plenty of draft for the fire.

In respect to the proportioning of the tubes to prevent interference with draft, this would of course only apply to new boilers designed for superheaters, as the sizes of the fire-tubes in an old boiler would not be changed if it were decided to install a superheater.

Mr. Watson still maintains, therefore, that the objections he mentioned are real objections, though under certain conditions they may become negligible, and it is always the best compromise of advantages and disadvantages which determines the choice in the matter and to make the best choice even minor disadvantages should not be overlooked.

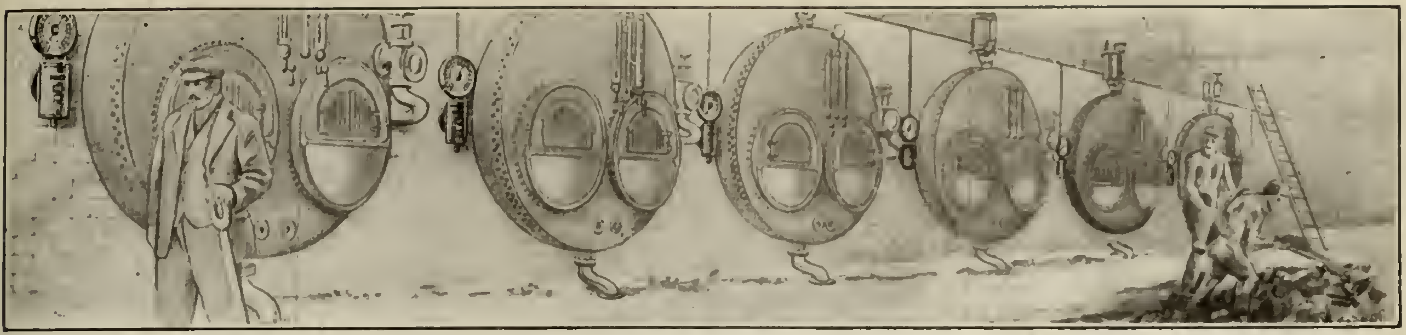
Mr. Watson was very glad to receive this criticism, and will be pleased at any time to receive criticisms or to hear of differences of opinion on any of the topics discussed in this series of lessons.

The Schofield Woollen Co. Ltd., Oshawa, Ont., are the owners of a power house being constructed at Oshawa.

The Municipal Electric light and power plant at Melville, Sask., was gutted by fire on September 2, causing a loss estimated at $100,000.

Tenders have been received by James McDole, secretary-treasurer, Elgin, Mich., for the contract of equipping the Elgin Consolidated school, Elgin, Man., with hot air plant.

Tenders are being received by Morrow & Beatty, general contractors of North Temiskaming, Que., for reinforced steel in connection with the hydro power development at North Temiskaming, Quebec.



Easy Engineering Lessons in the Power House

By M. BARRY WATSON, B.A.Sc., M.E.
Director of Engineering, Central Technical School, Toronto.

WET STEAM

SATURATED steam always contains more or less moisture in the form of minute drops of water suspended in the steam, much in the same way that small particles of water are suspended in the atmosphere during a fog, although there is seldom sufficient moisture in steam to make it visible like a fog.

The reasons for this water content of the steam are two in number. First, the steam in the boiler is formed on the heating surfaces, which are always below the water line. Thus the steam is formed as bubbles in the heating surface, which as they become large enough detach themselves from the surfaces where they are formed, float to the top of the water, where, as each bubble bursts, a fine spray of water is thrown off in all directions.

Most of this spray settles back to the surface of the water, or collects on the sides of the boiler shell where it drips down; the smallest particles, however, remain suspended in the steam, forming what we call "wet saturated steam."

Even if we should have perfectly dry saturated steam leaving the boiler, there is always a loss of heat from this steam through the headers and piping, on its way to the engines, no matter how well insulated they may be, though, of course, the better they are insulated, the smaller the loss of heat.

This loss of heat causes condensation of part of the steam, thus introducing moisture and causing wet steam to be supplied to the engines, etc.

The Quality of Steam

When we speak of the quality of steam we are referring to a method of expressing the proportion of moisture in the steam. This moisture is commonly called priming. It may be expressed in either of the following ways: First, as a percentage of the moisture in the steam. Thus suppose that in 100 pounds of wet steam, which is really a mixture of steam and water, we find there is two pounds of water. The steam may, in this case, be said to contain two per cent. moisture, or two per cent. of priming, or be two per cent. wet.

Secondly, as a percentage of dryness, thus, the above mentioned steam obviously contains 98 lbs. of dry steam in 100 lbs. of the mixture, and it may be said to have a quality of ninety-eight per cent., or to be 98 per cent. dry, or it may be stated that the quality is 0.98.

Quality Not Constant

In the majority of boiler plants the quality of the steam generated varies within large limits from time to time, as a result of various combinations of conditions of which the following are a few examples:

The inherently local nature of the generation and use of steam power prevents it from becoming a commodity. The contrary is true in regard to electric power. The characteristic of electric power constituting it a true commodity, the fact that it can be generated in bulk and sold at retail, the ease and flexibility of its transmission to a distance from its point of generation by means which can be extended at will, make natural the centralization of its generation.

When a boiler is carrying a heavy load, there is more steam being liberated from the surface of the water than when the load is light, thus there is bound to be more splashing and more moisture in the steam. Also the time between the liberation of the steam from the water and its entrance to the delivery nozzle is much shorter than when a light load is being carried.

In this way the small drops of water do not get as much time to settle out of the steam, and more and larger drops are carried into the steam header with the steam, because the velocity of the steam leaving the boiler is so much higher.

From the above reasons alone it is quite evident that at large loads, especially at a much above rated load, the priming will be greater.

When a boiler is nearly full of water, the surface where the bubbles burst is much closer to the steam outlet than when the water is low, thus more of the splash caused by the bursting of the bubbles will reach the steam outlet, and will be carried along by the current of steam.

In the case of horizontal cylindrical boiler shells where the normal water level is about the centre line, it is obvious that as the water rises higher its top surface becomes smaller in area, thus causing more agitation and splash for the same amount of steam generated. In this way it is clear that low water will give drier steam than high water.

Effect of Load

When no load is being carried by a boiler under steam, the water lies quietly at the bottom and any steam that is required to make up for condensation on the boiler top evaporates quietly off the surface of the water.

When, however, a load is being carried the greater part of the steam is formed under water on the heating surfaces and the space below the water line will be partly filled with water and partly with bubbles of steam.

It can therefore be seen that if the quantity of water in the boiler remains the same, the level of its top surface will be higher when carrying heavy loads. This effect is more noticeable the bigger and the more sudden the load, and it explains why the water level seems to rise in the gauge glass as soon as a sudden large load is put on a boiler.

In the control of feed water to a boiler it is usual to endeavor to keep constant fire conditions by supplying water when a small load is being carried and vice-versa.

This is, of course, fuel economy and makes available for peak loads of short duration the maximum boiler capacity, but if carried too far may cause trouble through priming.

Suppose that all load is suddenly shut off a boiler when showing half a glass of water. The water settles down and appears to lower its level perhaps to three-eighths of a glass. If now the pumps are speeded up until the boiler is showing, say, three-quarters of a glass or more, the fire can be kept pretty hot, ready for the next load, the excess heat being used to heat up the fresh water instead of to make steam.

Suppose now that a big load is suddenly thrown on the boiler, the level of the water will rise to near the top of the glass, and the combination of large load, high water, cool piping, etc., gives the most favorable conditions for heavy priming. This is especially so in horizontal cylindrical boilers.

Preventing Priming

Most of the cylindrical boilers built previous to the last quarter century had as an integral part a steam dome, the shape and position of which is familiar to all engineers, for the purpose of allowing the steam to be collected as far as possible from the surface of the water, where it is likely to contain least moisture.

Steam domes always constituted a weak point in boiler shell construction, and modern boilers do not have steam domes, in fact they are not permissible in many districts.

To cut down the amount of priming, leaving a modern boiler with the steam, a "dry pipe" is almost universally used. This consists of a horizontal pipe suspended below and attached to the main outlet nozzle of the boiler, capped at its end but perforated with numerous holes or slots along its top side for the admission of steam. Drops of water do not, therefore, splash directly into the flow of steam to the nozzle. Apart from the dry pipe the only piece of apparatus used in connection with the boiler to insure dry steam is the superheater which adds more than sufficient heat to the steam, after it has been removed from the boiler proper, to evaporate any moisture it may contain.

The superheater always, as a matter of fact, adds so much heat that there is still some to spare before the steam starts to condense.

To insure a supply of comparatively dry steam to engines and other apparatus, where superheat is not used, separators are made use of on the steam pipe feeding the apparatus, with the object of separating most of the moisture from the steam. Obviously the separators should be placed as close to the engine as possible to prevent much loss of heat through the walls of the pipe and the formation of more priming before the steam arrives at the engine.

Apart from the above, the obvious means to prevent priming are in the hands of the engineer in charge, namely, do not keep the water level higher than necessary, especially when handling big loads, and keep all steam headers and pipes as well insulated as possible.

Objections to Priming

Some of the evil results of excessive priming are so well known to engineers in general as to require no comment here. The chief disadvantage is, of course, the lowering of the efficiency of the engines through admitting water into the cylinder, thus increasing the water rate.

Also the danger of serious accident, such as blowing off a cylinder head, or breaking a piston or cross-head through water in the cylinder. There is also a direct loss in the heat carried from the boiler to the exhaust by the water.

Priming and Foaming

Some young engineers confuse priming and foaming. Such men probably have never really seen a boiler foaming, or else see it so constantly that they do not realize the difference.

They are, however, entirely different things, except that when a boiler foams, serious priming is bound to take place.

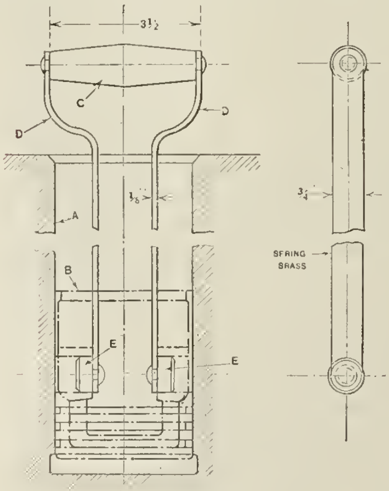
Foaming is caused by impurities in the water, which make the steam bubbles less easy to burst and to break away from the position where they first form. In this way the whole body of the water in the boiler becomes filled with large "bunches" of bubbles which break away and rise to the surface, causing violent churning of the water in the boiler.

At the surface the bubbles may pile up as high as the steam outlet when, of course, the priming will be so excessive as to do some damage.

Foaming always causes violent commotion in the boiler, which can be noticed by rapid changes in the apparent level in the gauge glass. The immediate remedy for foaming is to reduce the load in order that the bubbles may get more time to burst, while fewer of them will be made. The more permanent remedy is to blow down the boiler and fill it with clean, fresh water, thus reducing the viscosity and adhesive qualities of the boiler water so that the bubbles will burst easily.

PISTON FITTING TONGS

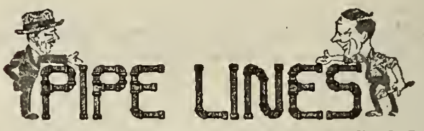
The tongs shown in the accompanying illustration are designed to facilitate sliding a piston up and down in a cylinder block when fitting the piston to the cylinder bore. The cylinder bore is shown in section at A, while the piston is represented by dot-and-dash lines at B.



Tongs for Fitting Pistons.

The tongs are made up of a handle C and two straps D made of spring brass. To the end of each of the spring strips is riveted a small plug E. These plugs are made about 0.005 inch smaller than the wrist pin hole so they can be easily inserted.

In attaching the tongs to the piston, it is only necessary to press the two straps together, insert the ends in the piston, and then allow the straps to spring back so that the plugs E will enter the wrist-pin holes. — FRANK OWEN.



PIPE LINES

UNCOVERED IN ANY OLD SPOT

The starting torque of an induction motor varies as to the square of the voltage at its stator terminal, that is, if the voltage is reduced by two, the starting torque will be decreased by four.

* * *

Have you ever noticed that about the time you grow chesty and hold your head high, you step on a banana peel you accidentally dropped?

* * *

Unbalanced voltages on a circuit supplying an induction motor may cause the machine to operate at a high temperature, even when only partly loaded, due to the motor acting on a voltage balancer.

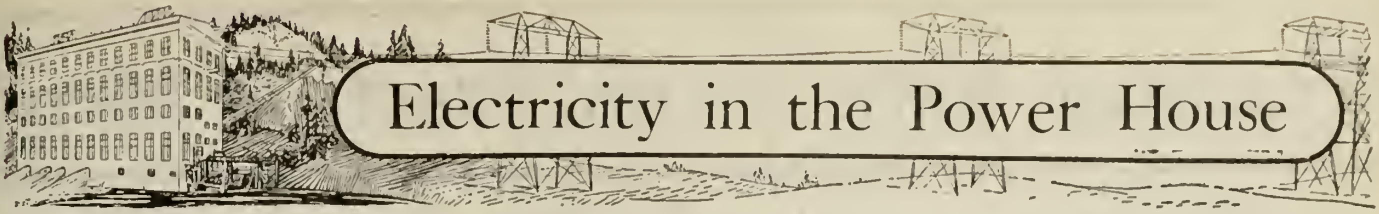
One thing can be said for wood alcohol —no one ever inherited a taste for it.



Electricity in the Power House

By J. A. BURNETT, M.E.I.C., Consulting Engineer, 205 St. James St., Montreal.

THE SYNCHRONOUS MOTOR

THE synchronous motor is now receiving special attention from manufacturing companies and it is satisfactory to note that the starting conditions have been simplified, no manipulation of switches being required.

This equipment is now almost as simple as the induction motor. Recently there have been installed in Ottawa two 200 h. p., synchronous motors, 164 r. p. m., direct connected to refrigeration compressors.

These are self-starting with auto-transformer taps at 80 per cent. line voltage. The starting rush of current is said to be 150 per cent. of full load, and time to accelerate and attain full speed, 50 seconds.

In case a synchronous motor is installed of a certain rating, for power factor correction, this equipment will simultaneously deliver about 50 per cent. in mechanical load, at a trifling additional loss as compared with an induction motor.

Driving Line Shafting

The synchronous motor may be used to drive line shafting when the starting torque required does not exceed, say, 50 per cent. of the normal rating of the motor. The synchronous motor may also be used to drive centrifugal pumps or fans when the pull in torque demanded near synchronous speed does not exceed approximately 40 per cent. of the normal rating of the motor, and use is made of a suitable low resistance squirrel cage winding, which decreases the starting current and increases the pull-in torque.

The synchronous motor is especially adapted for the direct drive of low speed air compressors, since these generally require about 50 per cent. of normal torque for breaking from rest and there is seldom difficulty experienced in pull-in torque requirements. Further, an induction motor for such low speed has a very low power factor.

The cost of the synchronous motor is considerably in excess of the induction motor, however. It is usually installed in a plant in order to raise the plant power factor to contract requirements.

Typical Connections

The diagram shows typical connections for this type of motor, with self-starting features.

As regards the operating features of this type of equipment, it may be noted that it is mostly a case of "built right—run right."

The exciter is usually furnished by the manufacturer, direct connected, making a very compact unit.

For example, a 75 h.p. synchronous motor recently installed by the writer was run at 1,200 r.p.m. and was provided with a 2½ k.w. exciter.

The self-starting feature is usually due to the fact that the current is applied to the stator (field). The motor is permanently connected to the exciter armature, which provides the slight external resistance necessary to give the rotor the desired starting torque.

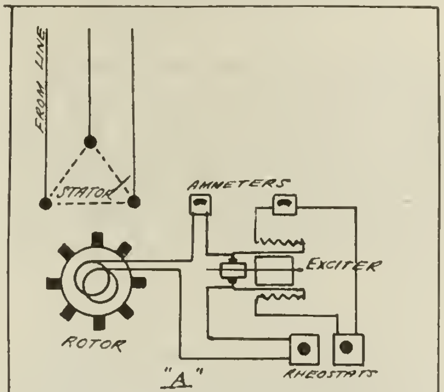


DIAGRAM OF CONNECTIONS FOR SELF STARTING SYNCHRONOUS MOTOR

The amount of excitation required is usually 3 per cent. of synchronous motor rating, and while the exciter is a comparatively small unit by itself, it is of great importance to select a well designed and well made exciter.

The temperature of any part of the machine should never exceed 90 deg. Centigrade. This is the absolute "dead line." In case this temperature is exceeded the insulation will deteriorate rapidly and the life of the machine will be shortened.

In case a machine shows signs of distress due to overload, the application of an ordinary 12 in. electric desk fan, at one end of the rotor or stator, will send a current of comparatively cool air through the machine, giving the desired relief.

A few spare stator (armature) coils should be kept on hand so that there will be no undue delay in making replacements—in case of breakdown due to lighting or overload.

The mechanical drives may be direct connected; belting; chain or spur gearing. In case direct connection is used, it is well to ascertain if the mechanical load is not excessive at time of starting, in which case a clutch cut-off coupling may be necessary to ease off at starting.

New Equipment 40
Ljunstrom Air Preheater

Plans are being prepared for power development at Hemmings Falls, Que., for the Southern Canada Power Co., 20 St. Nicholas St., Montreal. Bids will be asked during September.

The following contracts have been awarded in connection with the $11,750 boiler house being erected for the Royal Alexandra Hospital, Edmonton. Heating, Standard Plumbing & Heating Co.; electric, Carey Electric Co.; both Edmonton firms.

Work on the power development plant at St. Albans, Que., is going forward, and the owners, La. Cie Hydrolique de Portneuf, are in the market for two generators, 2,000 K.W. motor and turbine. The general contractors are the Estru & Conradi Construction Co., St. Catharines, Ont.

Practical Ideas From Practical Men

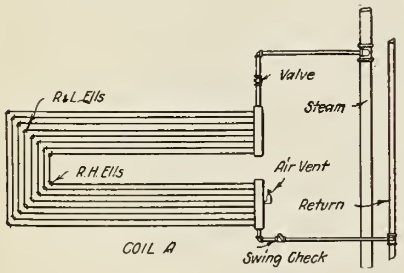
WALL COILS

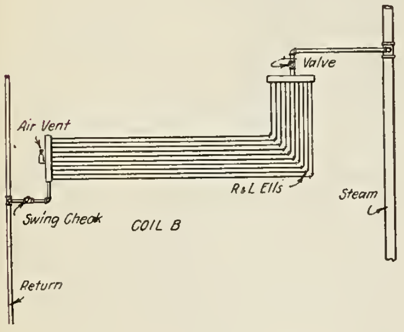
THE engineer is often called upon to increase the radiation in sections of a plant and in this connection there is an infinite variety of methods of piping wall coils. The object to be attained, of course, is free and unrestricted heating of the entire surface, and the freedom of the coil to expand and contract without strain.

Figs. 1, 2, 3 and 4 show two-size steam coils, on a low-pressure gravity system, having a control valve on the inlet side of each set, and a check valve and air vent at each return.

Coil "A," shown in Fig. 1, is a "U" shaped miter coil. This design is good where there is a minimum of wall length, and a large amount of height, and is of advantage where it is desired to keep the supply and return risers together.

Coil "B," in Fig. 2, is an ordinary "L" shaped miter coil, having supply riser at one end, and the return riser at the opposite end.





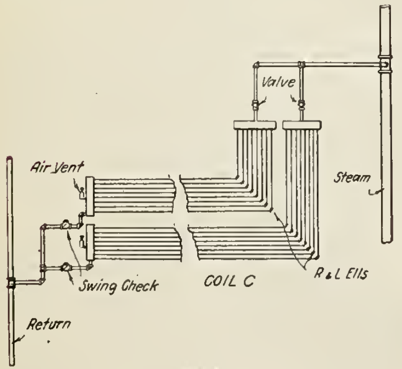


Fig. 3

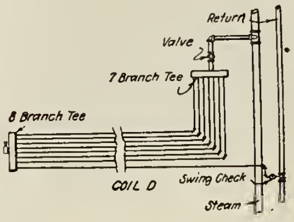
Coil "C" in Fig. 3 is a double "L" shaped miter coil with supply and return risers at opposite ends. This grouping is good where close control in individual units is desired, it being supplied with two sets of control valves, and two sets of check valves and air vents.

Coil "D" in Fig. 4 has the supply and return risers together, and is of interest because of the manner in which the return is run; it is the lower pipe of the coil, pitching opposite to the coil, and the unit made up with a seven-branch tee at the supply end, and an eight-branch tee at the return end.



In all coils, the standard method of connecting the check valve four or five inches below the return of each coil is followed. This leaves a head of water, to help in opening the swing check.

VOLTAGE REGULATOR TROUBLE

The automatic voltage regulator for alternating generators is usually somewhat puzzling to the power plant engineer, especially if it is new to him. Recently, a regulator was added to an industrial power house to regulate the voltage of two 1,500-kw. generators, the regulator controlling one of two 75-kw. exciters. It was found desirable to have a regulator on account of the fluctuating nature of the load and to prevent disturbance on a tie line connecting the station with a larger industrial power plant.

The behaviour of the regulator was somewhat erratic. For a time it would function perfectly and then apparently would suddenly go wrong and the generator would drop its load and the tie-line switch between stations would kick out before the generator could be cleared from the line.

It was found that this condition usually occurred when the generator was running near full load, or when the load was shifted from one generator to the other preparatory to shutting down one of the generators. A careful check of the connections and adjustments of the regulator indicated that the trouble was not in the regulator itself. As the characteristics of the generators were standard, possibility of trouble from that source was dismissed.

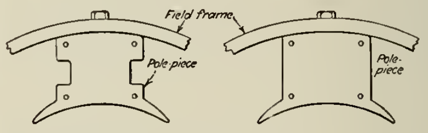
Attention was then centered on the exciters, which were furnished originally with overcompounded fields and whose maximum voltage was 150 at full load. In order to adapt the exciters to the regulator, it had previously been necessary to change the compounding shunt of the machines so as to give a slightly drooping characteristic to the voltage curve of the exciters. This was necessary since an overcompounded exciter will not allow a regulator to function to properly control the voltage of the system.

This change cut down the maximum voltage of the exciter to 130. It was necessary to leave some of the main field rheostat of the alternators cut in the field circuit in order to regulate the distribution of wattless current between generators, consequently it will be seen that some of the 130 volts remaining would be lost in this rheostat.

By cutting the regulator out of circuit for a few days and restoring the overcompounding of the exciter, it was found that a maximum of 140 volts was required with the main-generator field rheostat set in the position determined for proper operation in connection with the regulator.

Referred to Manufacturer

As the exciters were of the same make as the automatic regulator, the data secured from the foregoing tests were referred to the manufacturer to secure a remedy for the trouble, as apparently nothing further could be done by the operators. The manufacturers supplied new polepieces, Fig. 2, for each exciter to replace those which were originally installed and which, when the machines were dismantled, were found to have a reduced cross-section at one point. The new polepieces therefore allowed a lower reluctance in the magnetic circuit, giving a greater amount of magnetic flux with the same shunt winding. The exciters, after being fitted with the new polepieces, gave about 155 volts at no load and about 145 volts at full load when operating as a shunt machine. The regulator and the various rheostats were adjusted with the new voltage characteristics of the exciters and have given satisfactory regulation and no trouble has been experienced since the higher voltage has been available from the exciters.



The cause of the generator dropping its load under the conditions described, was evidently due to some sudden increase of load either from starting a large motor or a decrease in voltage of the main generating station. This increase of load, coming on when practically the maximum field current available existed in the generator field, caused a sufficient demagnetization of the generator field to lower the voltage of the motor driving the exciter, which in turn, by a reduction in speed further lowered the exciter voltage.

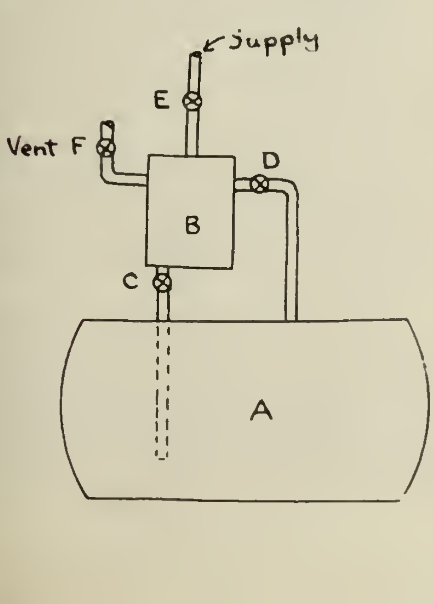
This condition acting cumulatively would quickly drop the station voltage to zero after the field of the generator was reduced to an unstable point with respect to its load. When the exciter has a sufficient surplus of voltage to increase the alternator's field current, any sudden demagnetization of the generator field, due to increase of load, is counteracted and equilibrium is obtained under almost any condition whether operating as an isolated station or tied up in with other stations. To illustrate this effect with the voltage regulator cut out, a 200-hp. motor driving an air compressor was started, the generator carrying 1,200 kw. on an isolated system. Without changing the field rheostat setting, the voltage dropped from 2,200 to 1,400. When the voltage reached 1,400, if the exciter voltage was not raised, that of the generator dropped from the 1,400 point to zero. The generator speed variation was less than 1 per cent. during the tests, therefore it could not have been in any way responsible for the drop in voltage.—TORONTO HYDRO ENGINEER.

A SIMPLE BOILER FEEDER

The figure herewith shows how water can be fed into a boiler under pressure without the use of an injector or pump of any kind.

"A" is the boiler that is to be fed with water. "B" is a tank or vessel capable of withstanding as high steam pressure as the boiler itself.

Close valves "C" and "D" and open valve "E" and vent "F" so that tank "B" will fill with water through the supply pipe. Then close valves "E" and "F" and open valves "C" and "D." Steam will enter "B" through the valve "D" and the water from "B" will flow downward through "C" due to gravity, because the vessel "B" is now nothing more or less than a part of "A" and since water naturally seeks its level in pressure vessels, as well as in the open atmosphere, it will flow downward, "B" will empty, and the water level in "A" will be raised. After "B" is empty, close "C" and "D" again, and open "E" and "F" and repeat the above process.

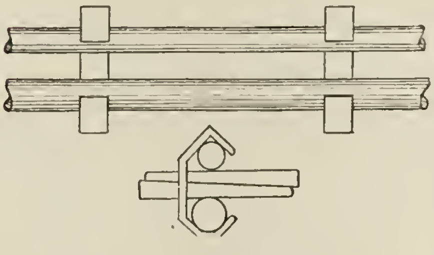


The writer is informed that a boiler-feeding device of this kind is now on the market, and that it is proving to be a success on large as well as small boilers. Its simplicity should certainly attract attention.

It is well to note in this connection, however, that some steam is required to do this work. When all of the water is emptied out of "B," that vessel is full of steam, hence the volume of steam used is equal to the volume of water fed into the boiler. It is, therefore, a simple matter to compute the amount of steam required to feed a given quantity of water into a boiler with this apparatus.—W. F. SCHAPHORST, M. E.

STRAIGHTENING LINE SHAFT

In every factory where line shafting is employed for the transmission of power it is quite common for a length of shafting to become buckled, due to bad alignment or to hot bearings. If bad alignment is the cause, it is obvious that when re-erecting the shaft after straightening, care must be taken, by adjusting the hangers, to ensure that the alignment is made perfect.



Fixture for Straightening Line Shaft.

A simple straightener which the writer has tried out is shown in the illustration. It is necessary to take the shaft down and if there is a lathe with a bed sufficiently long it should be set between the centres. If this is not possible a couple of Vee blocks resting on the floor will serve the purpose, although they are not as convenient because of the difficulty of rotating the shaft, which is necessary in order to locate the high places. It is advisable to screw a steady to the floor on which the hand can rest while holding a piece of chalk.

The straightening device consists of two forged steel pieces two to three inches wide. These hooks are suspended from the line shaft, the bend being downwards. On the bottom hooks a piece of straight shafting of larger diameter than the shaft being straightened is placed, or, for preference, a short length of carbon steel may be used. Folding wedges are now driven between the two shafts. A single wedge may be used but it will be inclined to slip back. It is necessary to make the shaft convex on the top side to secure a permanent set. While in tension the shaft must be struck several times with a hammer on the top side. The operation may have to be repeated several times before the flaw is eliminated.—J. McLACHLAN.

FROZEN BRINE COOLER

Some time ago in a small plant where a 10-ton refrigerating machine was used to carry a freezer, the brine cooler froze up. Sodium chloride, which has a fairly high freezing temperature, was used for brine instead of calcium chloride. The engineer asked me to come around, and on arriving I found that the centrifugal brine pump was frozen up and would not work.

I immediately turned on the condensing water and started the compressor turning over slowly. When the regulating or expansion valve was opened, the ammonia liquid flowed into the coil much faster than the compressor could remove the vapor, and as a result the coil pressure and boiling temperature rose.

The warm liquid ammonia from the receiver immediately thawed out the coils without damage, and the brine pump could be started. Although the pump was handling a rather bulky solution of ice crystals and salt solution, it was able to keep up the circulation. I suggested the use of 24 per cent. calcium chloride solution, which has a freezing temperature of —17 deg. Fahr.

The engineer could not understand how it was possible to thaw out the brine by running the compressor. I explained to him that the hot ammonia liquid from the receiver entered the shell cooler at about 80 deg. Fahr., and, being much hotter than the brine, of course warmed the latter until the solution was in condition to be handled by the pump.—GEORGE LEA, Hamilton, Ont.

TWO MOTORS ON LOAD

Two similar direct-current motors may be successfully operated in parallel to drive the same load from a single controller, provided their pulley or gear reductions are such as to drive the load at the same speed.

In special cases where a motor of proper voltage rating has been unavailable, two motors of half the line voltage rating have been connected in series and operated from a single controller, as if they were a single motor of proper voltage rating. Where motors are to be operated in series, it is necessary to connect them to the same load, otherwise their speeds will be unstable and one of the motors may even stop. This will cause full-line voltage to be applied across the running motor, which will attain a dangerous speed.

With squirrel-cage-type alternating-current motors, aside from the motor ratings and speed requirements, no special precautions need be observed when it is purposed to operate two motors from the same compensator, especially if the motors are to drive the same mechanical load. When they drive different mechanical loads, the motors may be started one at a time. In some cases a number of motor connections have been arranged to start each motor individually from the same compensator. In this case a double-pole switch is used to connect the motor to the compensator for starting, and after it has been brought up to speed the switch is thrown over to connect the motor directly to the line. Where slip-ring motors are to be applied to the same load and operated from the same controller, there arises a condition that must be observed, otherwise the blowing of fuses may render operation entirely impracticable.

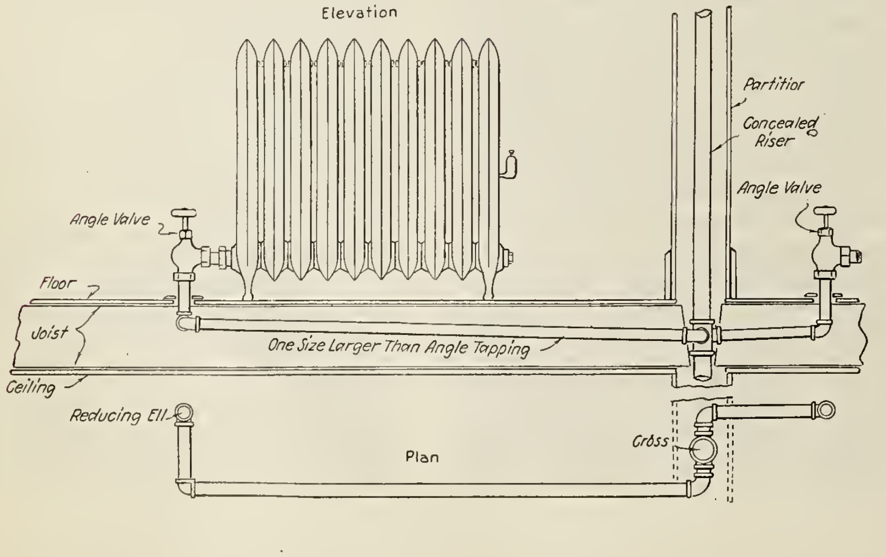
Since each rotor generates a voltage, they are similar to two alternating-current generators and must be treated as such when connected in parallel. The rotors will have to be phased out and connected together, in the same way that two alternators must be when the proper rotor positions have been located, they must be permanently connected together mechanically, otherwise they may get out of phase during starting and will produce a condition similar to connecting two alternators in parallel out of phase.

Heavy currents, could circulate between the two rotors without going through the starting resistance. Unless it is necessary, it will be found a good practice not to try starting two such motors in parallel from the same controller, since they will require careful adjustments for satisfactory starting.

A. R. K.

BRANCHES UNDER FLOOR

There is shown in the drawing an elevation and a plan view of a riser for a one pipe steam job, having two connections. Provision is made, by placing the cross longitudinally with the partition, for expansion of the riser. This is necessary if the riser serves a building over three stories high; one of three stories or less may omit the provision for vertical movement of the riser from the radiator supply branches, and take care of the small movement in the branch from the main in the basement.



But the method shown in the drawing is very good practice on any concealed riser job.

If there is likely to be considerable movement of the riser, connection may be made to the farthest end of the radiator, as shown at the left, and the branch given a good pitch and increased one size, making reduction at a reducing elbow at the base of the "stub" immediately below the angle valve. If there is but little or no movement of the riser, the branch may be short, connected to the nearest side of the radiator as shown at the right, and the branch may be of the same size as the angle valve it supplies.

If it should happen that there is an excess amount of radiation which would tend to condense a large amount of steam in the radiator, the top connections sometimes cause a large amount of condensation to collect in the bottom of the radiator, which would in severe climates at low temperatures cause the condensation to freeze.

Using the steam type radiator with bottom connection prevents this.

HUNTING TROUBLE

The writer recently took part in a trouble hunt which illustrates the well-known fact that the simplest things are often the easiest to overlook.

The trouble was in a small brine system, two units of which were not producing satisfactory results. The plant was not a new one but had been in use for several years and up to a few months ago gave good service.

There was nothing unusual about the layout, a machine and brine tank in basement, brine circulated by centrifugal pump directly connected to 1,200 r.p.m. motor, 2½ in. suction, 2 in. discharge.

There were four cooling rooms or boxes in this system, three of which were on the first floor and one on the second floor. Two of the boxes on the first floor were small and were located close to the brine pump. These boxes worked nicely. The other box on the first floor was a fairly large box and located about 100 feet or more from the brine pump. The box on the second floor was the same size and located directly above the large box on the first floor.

Simplified Piping

The suction line to the brine pump connected directly into the end of the tank, about 3 inches from bottom. It was a straight run without obstructions of any kind except a gate valve. The discharge went straight up from pump to ceiling of basement, about 8 feet, where it was split by a bull-headed 1 in. x 1½ in. x 2 in. tee. The one-inch line ran straight out about 10 feet, where it was split by a bull-headed ¾ in. x ¾ in. x 1 in. tee. Each of the ¾ in. lines ran to one of the small boxes. The 1½ in. line ran back to the large boxes and in the 100 feet of pipe there were 10 elbows. The line could have been put in with 6, but 10 were used. The line went up into the large box on the first floor where there was a 1½ in. x 1 in. x 1 in. running tee. Our one-inch line went up to a box on the second floor, the other feeding the coils in box.

The return line was practically a duplicate of the feed line, except that it entered the other end of the tank about 6 inches below the top of the tank.

The arrangement of the coils in the boxes were the same in each box. There were two stacks of coils, one on each side near the top of the room. All were made from 1¼ in. pipe, using 6 in. centre return bends. The feed supply entered at the bottom and circulating up through the coil on one side of the room then crossed over and went down through coil on other side and out through return line through floor. The feed and return were the same size, ¾ in. on the small boxes, 1 in. on the large boxes.

Hunting the Trouble

The complaint was that the box on the second floor would not frost and that the first floor box would not get cold, although the pipes would frost. When the complaint was first made the brine tank had been refilled and the brine level was above the return discharge. Thinking that the trouble was caused by the higher coils air locking, they were advised to remove enough brine to clear the discharge.

It was not convenient to do this for a time and as nature helped out with some zero weather the trouble was allowed to ride for a while. When the discharge was cleared there was no improvement, however, and the trouble had to be located elsewhere. The amount of brine returning to the tank seemed very small and when the feed valves on the two small boxes were closed it almost stopped. This seemed to indicate a stoppage in the brine line serving the two large boxes.

There was a union just above the feed valve in the large box on the first floor. On disconnecting this it was found that the feed valve could be opened wide yet the brine only flowed over the top of the pipe, no pressure at all. When the feed valves on the two small boxes were closed it made no difference. The brine

(Turn to page 39)

Every-day Problems With Answers

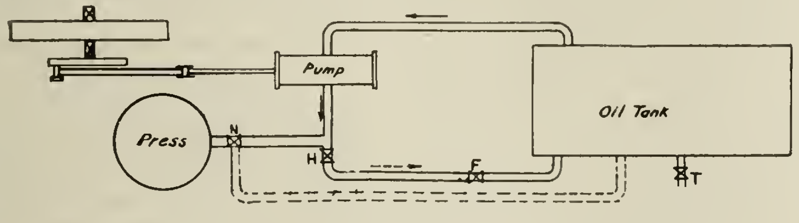
Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

OIL PRESS

THE accompanying sketch shows a power operated oil press, which for some reason or other fails to operate.

The method tried so far is to first fill the tank with oil, then turn on the air pressure and force the oil into the pump. After the ram has moved up to the work the air supply to the tank is shut off by means of the three way cock T and the air pressure relieved from the tank. The pump is then started to obtain the required pressure on the ram, but so far it has not been possible to obtain any pressure by the pump. The system works only with the air pressure on the oil tank.

At present there are no check valves in any of the lines. Would it help any if check valves were placed on the suction and the discharge sides of the pump? Is there any cause other than a leak in the pump which would cause the failure to operate?—B. HAWKINS, Hornepayne, Ont.



Answer:—If the sketch you send is complete, the failure of the pump to operate the ram is quite evident. You do not mention in your letter anything in regard to the globe valve F on the overflow line from the press. Assume that the valve F is open and the pump started. There will be a clear passage for the oil from the pump to flow back directly into the oil tank as shown by the dotted arrows; no pressure then could be produced in the pipe line leading to the press. If the valve F is closed, then, provided the pump is in working order, pressure will build up on the ram, but it might be disastrous to the pump since there is no provision to relieve the pressure. The pump would last about one stroke if the valve F was closed, because the eccentric or the cylinder would give way.

Pressure will build up in the whole system with air pressure on the oil tank regardless of whether the valve F is open or closed. This explains the working with the air and the failure of the pump.

To make the system work, a relief valve should be placed in the overflow line at H or in place of the globe valve F, and set to the pressure required on the ram. Pressure will then build up on the ram and any oil pumped in excess of that required by the press will escape back to the tank through the relief valve. The globe valve F must never be closed when the pump is in operation.

If the pump valves are in bad condition it would be helpful to put check valves in the suction and the discharge lines; if the pump is in good condition there is no need of them. To cut down the power required by the pump when the press is not in use, a 3-way valve should be fitted as shown at N, which will shut off the press and allow the oil to flow back to the oil tank shown by the dotted pipe line.

LOOSE PULLEY HEATS

I have considerable trouble with a loose pulley on a small machine. The pulley keeps binding on the shaft and finally gets heated up so that it binds sufficiently to make the whole machine move. It will run quite free for a short time after taken off and oiled, but the trouble soon starts again. Can you suggest a remedy?—R. INNES, Winnipeg, Man.

Answer:—There may be several causes for the heating of a loose pulley on the shaft. A common cause of trouble is dirt getting in the bearing between the pulley and the shaft, causing some cutting and making a rough surface. When such a condition once starts it is almost impossible to keep the pulley from heating. The remedy is to smooth the shaft or replace with a new one.

Belts that are too tight often cause heating of the loose pulley, especially if the speed is high. The pressure may be sufficient to break through the thin film of lubrication and once a slight heating has started the oil becomes thin and runs off, leaving the bearing practically dry, when further heating is bound to result.

As a remedy for your troubles the following suggestions are offered:

Remove the pulley and make sure that the shaft and the bore of the pulley are smooth and clean.

If the belt is too tight add a short piece and run the belt as loose as possible to handle the work satisfactorily.

Fit a grease cup to the pulley and use a good grade of grease. If oil is used in a grease cup centrifugal force will, unless the speed of the pulley is very low, prevent it reaching the bearing.

If none of these methods is successful in preventing heating of the pulley, then some special form of bearing will have to be used in the pulley, such as ball or roller bearing.

GAS ENGINES

If the compression chamber of a gas engine is made smaller, will it give more power? What effect has altitude on the power of an internal combustion engine? What effect has the brine of a refrigerating machine on the cooling action?—W. F. JOHNSTON, Medicine Hat, Alta.

Answer:—Making the compression chamber or clearance volume in a gas engine smaller results in an increase of compression pressure.

The thermal efficiency of an internal combustion engine increases with an increase in the compression pressure. In this way, by an increase in efficiency, the power of a given engine is increased.

In addition, increased compression pressure results in an increase of the power per unit of volume of piston displacement, and permits the use of a leaner mixture which otherwise could not be readily ignited.

Thermally, it is advantageous to increase the pressure, but practical considerations limit it. If the pressure at the end of the compression stroke is excessively high, with correspondingly high temperatures, pre-ignition may result. Pressures in common use seldom exceed 150 lb. per sq. inch at the end of compression.

The formula for the efficiency of a gas engine is

$$\text{Eff.} = 1 - \left(\frac{P_1}{P_2}\right)^{\frac{K-1}{K}}$$

where P_1 = pressure at the beginning

of compression, P_2 = pressure at the end of compression, and K a constant.

$\frac{P_2}{P_1}$ is known as the compression ratio.

Using a value of K as 1.35 the theoretical thermal efficiency varies from .355 for a compression ratio of 3.5 to 1 to .553 for a ratio of 10.0 to 1.

Actually the increased efficiency resulting from high pressures is partially nullified by increased losses past the piston rings and the slightly increased friction loss.

The net effect of making the combustion chamber smaller, provided, of course, that the resulting pressure at the end of compression is not sufficient to cause pre-ignition, and if the rings are in good condition, will be an increase in power from the engine.

At high altitudes the atmospheric pressure is much lower than at sea level, or the air is less dense. The displacement volume of an internal combustion engine remains the same, but at high altitudes, due to the decreased density of the air, less weight is drawn into the cylinder on the suction stroke, therefore the power from each explosion is less than it would be for the same engine working at sea-level.

Makers of gas engines guarantee their engines to give a certain rating at sea level and advise purchasers to allow about 3 per cent. loss of power for each 1,000 feet above sea-level.

The brine in a refrigerating system acts as a heat carrier, to remove the heat from the room, or the substance being cooled, and give it up to the cool ammonia, in the case of the ammonia machine. Direct expansion coils may be used and brine dispensed with entirely; in fact this is often done. Brine is, in many places, a convenient method of carrying the heat, as it can be pumped long distances.

LINING UP CORLISS ENGINE

I would like to see in Power House a description of the correct method of lining up a Corliss engine.

Could a Corliss engine be changed to a throttling governor type by setting the grab claws solid? — A. E. SPEAKMAN, Glassville, N. B.

Answer:—In lining up a Corliss engine the chief consideration is to get the shaft at right angles to the direction of travel of the piston and cross-head.

The method following is one used and recommended by the Goldie and McCulloch Co. of Galt, Ont.

If the engine is in running condition and the alignment is to be checked, the cylinder head must first be taken off. Remove the piston, the cross-head and the connecting rod.

Stretch a line tightly through the centre of the cylinder and the stuffing-box, past the centre of the shaft as shown in the drawing.

A silk fish line or a fine wire tightly stretched will answer the purpose.

The line can be held in the centre of the cylinder at A by means of a clamp bolted through one of the cylinder head bolts. Caliper this very carefully; it must be as near the centre of the cylinder as it is possible to get it. Then do the same at the stuffing-box. The line then should pass by the centre of the main shaft.

The alignment of the cross-head guides may be checked with calipers, but if the engine has been properly constructed in the shop it is not necessary to do any checking in the field.

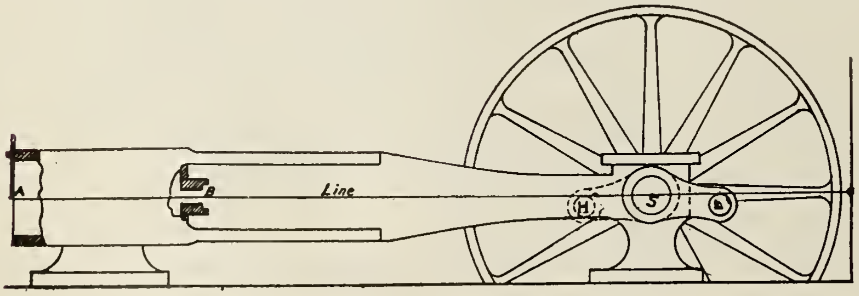
Roll the crank until pin is at the position L just touching the line. With the line in the centre of the crank pin bearing caliper the distance between the face of the main shaft and the line. Then roll the shaft until the crank is in the position H (shown dotted). Caliper the distance between the line and the end of the shaft as before.

If the distance is the same in both cases the main shaft in then in its proper place. If not the axis of the shaft is not at right angles to the direction of travel of the piston.

If all parts are in correct alignment the line though the centre of the cylinder and the stuffing-box will pass the centre of the shaft and the centre of the crank pin bearing in either position L or H.

A Corliss engine can be changed to a throttling governor type by setting the grab claws solid. The cut-off then is fixed as in the simple throttle governing engine.

It is advantageous to have a fixed cut-off if the engine is to work at light loads for long periods.



PREVENTING SCALE

For the past eighteen months I have been using potato water in boilers to prevent scale from forming, with good results. The potatoes are boiled along with peelings from the kitchen, and the water strained off and put in the tank from which we pump the feed water.

I have been informed that potato water is very injurious to boiler plates and tubes. What is your opinion on the matter?—W. J. McFADDEN, Ontario Hospital, London, Ont.

Answer.—There appears to be a difference of opinion regarding the use of potato water in boilers.

A prominent consulting engineer says he sees no reason why potato water should do any damage to a boiler; on the other hand, he knows of nothing in it which could do much good in preventing or removing scale. A small amount of soda ash, in his opinion, is much more effective, and certainly much less labor is required in preparing it.

An engineer in one of the large boiler shops in a Western Ontario city has used potato water in his boilers for years. He claims that so far no damage has resulted and that it cleans the boilers thoroughly.

H. P. Stephens, of Toronto, does not recommend the use of potato water, claiming that it causes pitting and corrosion. The corrosion may go on, and being under the surface, may be very serious before it is detected. The starch in the potato water, he claims, prevents scale by forming a scale itself, which is even worse than ordinary scale in preventing heat from entering the water.

BOILER BRIDGE WALL

In a horizontal return-tubular boiler setting, is 0.3 of the boiler diameter sufficient clearance between the top of the bridge wall and the bottom of the boiler? Where bituminous coal is used. has the flat-top bridge wall any decided advantage over the older type which curved like an inverted arch following the shape of the boiler?—JAMES ATKINS.

Answer:—In an ordinary setting of a return tubular boiler, the furnace bridge wall is for the purpose of preventing the coal from falling off the grates, and for baffling the draft to force the air to pass up through the whole fuel bed.

The shape of the wall, whether flat on top or curved to correspond with the shell of the boiler, or whether the wall is provided with vertical or with sloping sides, appears to make little difference.

The area over the wall must be at least large enough not to check the draft afforded by the total tube area. With a flat top for the bridge wall, sufficient area is obtainable when the distance from the top of the wall to the under side of the boiler is 25 per cent. of the boiler diameter.

A flat wall is easier to build and is preferable to an inverted arch form. as the latter is more likely to cause greater concentration and impingement of the heated gases against a girth seam of the boiler.

ENGINE POUNDING

We operate a 28 x 48-in. Corliss engine that has been running over for 15 years and recently had to reverse the engine; that is, it now runs under. The engine has a loud knock in the main journal bearing. How can we get rid of the trouble?—G. S.

Answer:—When running over, transmission of the load from the piston to the connecting rod causes the crosshead to exert pressure on the lower guide in addition to the pressure from the weight of the crosshead and connected parts.

When the engine was reversed, the pressure of the crosshead, less the pressure due to the weights, was transferred to the upper guide. Hence, in runing under, the crosshead is not held as rigidly to the guide, and that may be the initial cause of pounding, which is taken up by the main bearing. The remedy for this trouble from the crosshead would be to obtain good alignment of the guides and centre the crosshead with the least possible clearance between the crosshead and guides consistent with maintaining good lubrication of the upper guide.

From long time running, the crosshead pin, crankpin and main journal and their bearings would become worn out of round, and from reversing the engine there would be opposite direction of wear and different distribution of pressure, and if the pins, main journal and all bearings have not been trued up since the engine was run over, those repairs should be made before it can be expected to get rid of the knock in the main bearings by simply adjusting the crosshead.

MOTOR IN STEP

Can an induction motor, which has the same number of poles as the generator that supplies the power, run at the same speed as the generator—that is, at synchronous speed—or must there necessarily be some slip even at no load? If the rotor of the induction motor must run slower than synchronous speed, how does a synchronous motor get into step when started as an induction motor?—A.B.

Answer.—In a polyphase induction motor the relation of the currents in the stator windings are such as to produce a revolving magnetic field. This field revolves at synchronous speed and is equal to 120 times the cycles per second divided by the number of poles.

On a 60-cycle circuit the magnetic field of a four-pole motor will revolve at (120 × 60) ÷ 4 = 1,800 r.p.m., and if the alternator supplying the power has four poles, it will also revolve at the same speed.

If the rotor of the induction motor was revolved at 1,800 r.p.m., its conductors would be moving at the same rate as the stator's magnetic field. Under this condition the conductors would not be cutting any of the lines of force and, therefore, would not have a current induced in them; consequently, the rotor could not develop and turning effort.

In order that the rotor conductors may cut the lines of force, it must run slower than the magnetic field. At no load the difference in speed will be small. At full load the rotor will run from 4 to 10 per cent. slower than the stator's field, depending upon the resistance of the rotor's winding.

When a synchronous motor is started as an induction motor, it cannot pull into step until the field switch is closed. When the motor is started the field switch is left open and the motor brought up to as near synchronous speed as it will come as an induction motor; then the field switch is closed and the motor pulls into step, provided it is not too heavily loaded.

If the motor has a low-resistance squirrel-cage winding in the pole faces, it will not be capable of developing a good starting torque, but can bring the load that it can start up to near synchronous speed, therefore will pull into step easily when the field switch is closed.

On the other hand, if the starting winding in the pole faces has a comparatively high resistance, the motor will develop a good torque, but the rotor will have considerably more slip than the low-resistance rotor. As a result the high-resistance rotor may not pull into step as smoothly as the low-resistance machine. In either case the field switch must be closed before the rotor can come up to synchronous speed.

WATER JACKET SCALE

How can a gas-engine water jacket be cleaned of scale deposited out of the cooling-water?—A. WHITE.

Answer:—The scale deposited out of most cooling waters can be removed by a solution of commercial muriatic acid and an equal quantity of water. Care should be taken that the solvent action of the acid is not continued to the extent of injuriously corroding the walls of the water jacket or other parts of the engine.

After application of the acid solution, the parts that have come in contact with it should be thoroughly washed with clean water.

CUSHIONING A PUMP

How is the cushioning of a duplex steam pump obtained and regulated?—ENGINEER.

Answer:—The steam cylinders are provided at each end with two sets of ports. Each outer port acts as the steam admission port and terminates at the end of the cylinder so as to guide the incoming steam into the clearance space behind the piston; and each inner port acts as an exhaust port and terminates nearer the middle of the cylinder.

When the steam piston passes over the exhaust port, no more exhaust steam can escape and, without cushioning valves, whatever steam is thus entrapped in the cylinder is compressed and acts like a cushion in bringing the piston to rest.

This compression may be excessive and, by means of hand-operated compression valves that connect the outer or steam ports of the cylinder with the inner or exhaust passages, the amount of cushioning can be reduced, by permitting more or less of the compressed exhaust to escape from the end of the cylinder through the steam passage into the exhaust passage.

Power Notes

The Northern Ontario Light & Power Co., Cobalt, Ont., is having additional electrical equipment installed in its plant.

Capital Electric Appliances, Ltd., Ottawa, Ont., has been incorporated with a capital of $25,000 to manufacture and deal in electric stoves, heaters, etc.

The Waterous Engine Works Co., Ltd., Brantford, Ont., have been awarded the contract for boilers in connection with alterations to the Military Hospital, St. Anne de Bellevue, Que.

Wallace & Aikens, Ltd., Winnipeg, Man., have been awarded the general contract in connection with the power house and laundry for Grace Hospital, Winnipeg, Man.

James, Proctor & Redfern, 36 Toronto Street, Toronto, consulting engineers, are preparing plans for a waterworks plant to be erected at Creemore, Ont., including mains, hydrants, valves, etc., and which will cost approximately $40,000.

The Port Arthur Shipbuilding Co., Port Arthur, Ont., has been awarded the contract for building the steel towers for the Hydro electric power lines between Cameron Falls and Port Arthur, Ont., to cost approximately $200,000.

Among those attending the convention of the Public Ownership League of America, held in Toronto from September 11 to 13 inclusive, were F. H. Malby, office manager, and J. G. Glassco, manager of the Hydro Electric Commission of Winnipeg, Man.

Work on the construction of a new gas plant for the Winnipeg Electric Railway is expected to commence shortly. The plant, when in operation, will be capable of producing approximately 2,500,000 cu. ft. of gas. Modern machinery will be installed which will effect savings that will warrant the capital expenditure. The plans at present are not quite completed, but it is expected that the contract will be awarded by the end of September, and it is understood it will cost approximately $1,000,000.

The W. R. Sexton Boiler Setting Co., 114 Grenadier Road, Toronto, have had a particularly busy season, the following work having been completed in the past few weeks: extensive repairs to the firebrick work in the power plant of the Robert Simpson Co., Ltd.; the installation of three Murphy arches for the Toronto Housing Commission, Bain and Logan Aves.; the installation of a new tempering furnace for hand saws in the plant of the H. Disston & Sons, Ltd., 2 Fraser Ave., Toronto, and repairs in firebrick work to travelling oven for the Telfer Biscuit Co., 139 Sterling Road, Toronto.

Comments in the Power Plant Field

DENIES INJUSTICE

ON PAGE 44 of the August 20 issue of Power House, George A. Brown, a well-known Toronto engineer, in an open letter, criticized the statements made by J. M. Brown, chairman of the Ontario Board of Stationary and Hoisting Engineers, at the banquet of the Canadian Association of Stationary Engineers, in the Hotel Carls-Rite, particularly stressing the statement:

"Do not worry, there will not be a surplus of engineers, as I watch the employment situation, and when there is a scarcity of engineering positions, I make the examinations harder."

The letter reproduced on this page, without comment, is the board chairman's answer to the stationary engineers of Ontario.

TEXT BOOK DATA

Many statements in text books are accepted by the majority of engineers without question. Practical experiment has shown that some of these statements are far from correct.

One in particular which I doubt is that 1-16 inch of scale covering the interior surface of a boiler will increase the fuel consumption from five to ten per cent., depending upon the character of the scale.

If this statement is correct, then scale is about the most heat retarding substance in the world. If the heat loss is so great, it would be instructive to tell readers where all this loss goes. Does the boiler setting absorb more heat than would be the case if there was no scale in the boiler or is it accounted for by a rise in the temperature of the escaping gases?

Experiment can be made to demonstrate the relative conductivity of scale and iron, but in actual practice, can it be demonstrated that a thin coating of scale will cause this great increase in fuel consumption?

I would imagine, if there is truth in the statement, that the external surface of steam pipes, heaters, etc., covered with a ½ in. thick coating of plaster material approximating the composition of scale, would be practically free from heat loss by radiation.

It is the discussion of doubtful questions of this nature in the correspondence section of engineering newspapers, such as Power House, which makes the paper of such great value to the engineer looking for helpful information different from the text book theories. Every engineers owes much of his success to text books and engineering schools, etc., but the correspondence section of the engineering journals hold a corner in the regard of the operating engineer which nothing else seems to fill, be-

THE BOARD OF STATIONARY
AND HOISTING ENGINEERS

ONTARIO
DEPARTMENT OF LABOUR

Spadine House, Spadina Cresc.,
TORONTO, September 11th, 1923.

Dear Sir:-

Our attention has been drawn to a letter in your August 20th issue of "Power House" written by George A. Brown, criticising our method of standardizing engineers' examinations, under the heading "Examination Tactics."

There are two factors that enter into the discussion of standardizing examinations, namely the minor factor of supply and demand, and the major factor of the qualifications of the average man to fill the position.

Considering the first mentioned, let us suppose there is a shortage of engineers, would it be good policy for the Board to make the examination of such a nature that none could pass it? For the Province to prosper, the factories must run, - but how are they to run if their power plants are shut down? And then again, supposing there is a surplus of engineers, should not the more diligent and proficient get the preference? However, such conditions do not change with every wind that blows, but extend over long periods and the standard of the examination does not change daily from this cause, as Mr. Brown pretends to believe. It is the minor factor but should, however, be taken into consideration.

The major factor is entirely in the hands of the engineering body. It is that the average candidate will be successful and all below him will fail. This puts the onus on the engineering class as a whole. If their average knowledge increases (which we are pleased to be able to say is the case) then the standard of the examination can be raised. Of course if the engineering class became dilatory (an event impossible to imagine when we study the fine intelligent class of men who are now going into engineering and the advantages they are taking of the many different courses of study now available) then nothing is left to be done but lower the standard of examination.

Under the heading "Not a License" Mr. Brown commences the paragraph with the sentence "Now, in regard to the license being a Certificate and not a license," we wish to call his attention to the fact that a Certificate may be a License but a License cannot be a Certificate. A License is simply a Permit while a Certificate denotes that the holder has certain qualifications.

With regard to regulating the number of hours an engineer should work. We wish to state that this Board has no power to make laws. Their duties are to carry out a certain law entrusted to their care which was passed by Act of Parliament.

We were pleased to read Mr. Brown's letter and are always glad to have criticism, providing it is of a constructive nature. Our aim is to make the Ontario Certificate the very best and ask the co-operation of the engineer.

I am

Yours very truly,

JMBrown

CHAIRMAN.

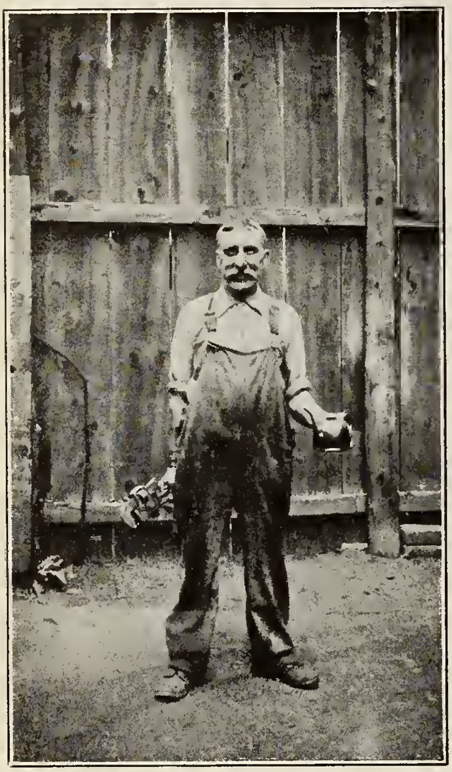
cause some little tip in each issue is of great value to someone or other.—JAMES E. NOBLE, 173 Macdonnel Ave., Toronto, Ont.

"ON THE JOB".

In the last issue of Power House I notice you request readers to forward you practical pointers and photographs.

Some years ago I used to answer many of the questions sent to Power House; and as I had a very limited education, I learned a great deal in this way, as well as by reading other articles in the newspapers. I always regret to hear of engineers who ignore the valuable information contained in Power House.

I have had twenty-three years' experience operating engines, water tube and return tubular boilers. I made an attempt to get a second class certificate, but owing to my lack of general education, failed.



JOHN QUINLIN,

On the job at the Brighton Laundry, 826 Bloor St. W., Toronto.

The photograph I am forwarding you was taken, as you will notice, "on the job." I was snapped just as I had finished tightening a fitting and oiling traps on top of a boiler, this explaining the pipe wrench in one hand and the oil can in the other.

It would be well for you to emphasize in Power House the fact of cleaning the smoke box on all boilers, as I have had a good deal of trouble in this way. I sometimes forget this myself, as it keeps me pretty busy keeping my plant running, but in the past three years there has not been a five minute shut-down except on Sundays.

With best wishes for the success of Power House.—JOHN QUINLIN, 276 McPherson Ave., Toronto.

R. J. Hoare, engineer of the Commercial Motor Bodies and Carriage Co., of Guelph, Ont., believes there is need of greater co-operation among the engineers of that city. He, however, is pleased with the progress being made by the local branch of the Federal Union of Stationary and Hoisting Engineers, which was started six weeks ago.

The present system of steam boiler inspection and granting of licenses in the province could be much improved, according to Mr. Hoare.

"I was eleven years in various plants without once having a government boiler inspector call on me. At present when an inspector makes a report the matter ends as far as the engineer is concerned. If anything is wrong, nothing is said. In many plants men are in charge who have no certificates or have lower grade ones than required by law."

* * * *

E. Cunningham, chief engineer of the Taylor-Forbes Co., of Guelph, Ont., says that the water in that city is extremely hard, but by proper use of sal soda he has no difficulty in keeping his boilers clean. For a 150 h.p. boiler he uses a pail of soda twice a week. The soda is dissolved in a pail of hot water and fed to the boiler through the feed water.

Mr. Cunningham in relating some of his experiences, mentioned trouble he had with low water in a horizontal return tubular boiler.

"The water in the boiler was up to the top of the glass, so the feed pump was shut down and the gauge blown down, the water at once rose again to the top of the gauge. After several blowings, the water was still high but as the load at the time was light, low water was not suspected. I happened to be around the condenser and back of the boiler, everything seemed to be unduly warm so I decided to test the water again and to shut down at once if I could not find the water level. On blowing down this time the water did not show in the gauge. When the boiler had cooled down, it was found that the top two rows of tubes were dry. A small piece of dirt had clogged the top connection, which accounted for the water rising out of sight in the glass. The last time when it did not show in the glass the level of the water in the boiler was below the bottom connection."

As it occurred on a Monday morning the explanation given by Mr. Cunningham was that dirt and sediment had been in the boiler and the first fire in the morning had stirred up the sediment and deposited some of it at the valve in the top water connection. The two top rows of tubes apparently acted as a superheater, which accounted for the unusual heat at the back of the boiler and around the condenser.

R. Farrelly, engineer of the Bell Piano and Organ Co., of Guelph, Ont., has been 18 years with the same company. He has no trouble in getting good steam coal at a reasonable price. Mr. Farrelly had trouble once with the packing in a hydraulic elevator. The packing would remain tight for only a few days then would start to waste water. As a last resource packing, made of waste twisted into a rope and well soaked with tallow, was tried. The packing was tightened every day for a week, after that it remained in good condition for years with no further attention. So well did the waste and tallow work, that the elevator had to be packed only twice in ten years.

* * * *

Percy E. Winfield, chief engineer of the Partridge Rubber Co., Guelph, Ont., thinks that for a steady load all day long, no plant can compare with a rubber factory.

"We use a lot of steam, but if the coal is good or only fair, we have little trouble in keeping up the pressure. I believe the proper way to fire is to keep the fires clean at all times, and not allow them to get dirty and do all the cleaning at once. It is easier on the firemen and the coal pile to clean frequently."

* * * *

W. T. Bishop, for the past twenty years engineer of Robert Stewart, Ltd., Guelph, Ont., finds many useful hints and practical ideas in Power House. Proper attention to small details at the right time will save the engineers hours of hard work later on.

"My motto is 'Keep the plant running'," he said.

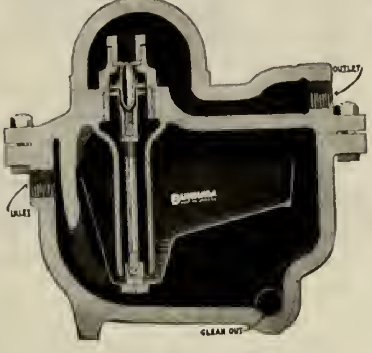
"In the lumber business, refuse is the chief fuel but often a small amount of coal is required. I believe that in the small plant, the use of a feed water heater will save fully 25% of the fuel. I keep the temperature of the feed water around 210 deg. Not only does this save fuel by decreasing the amount of heat required by the water but it removes some of the scale forming compounds before they get to the boiler, keeping the boiler clean and allowing more heat to get to the water."

A maximum voltage rating is usually given on the nameplate which merely indicates the strength of the insulation, and the transformer must not be used on voltages above that rating, but may be used on voltages below it. For instance, a transformer marked 6,900 volts maximum may be used on a 2,300 or 100-volt circuit but not on an 11,000-volt circuit.

Deposits formed in the cooling coils through which the circulating water flows, act as a heat insulator and also tend to reduce the amount of water passing through the coils. Generally such deposits can be removed by passing a solution of muriatic acid and water through the coils.

Dunham High Pressure Bucket Trap—Type No. 80

Quick acting - Powerful - Accessible !



There's nothing "draggy" about the action of this trap. The shape of the Dunham bucket and a short-coupled leverage obtain unusual power and speed. When the bucket is down and the trap is discharging, the inclined bottom stands practically in a horizontal position. As the water is forced out through the discharge tube from the bucket, and the bucket begins to rise from the buoyancy of the water surrounding it, all of the water on the bucket "shelf" is suddenly poured over into the water seal. As a result, the movement of the bucket is greatly accelerated in its closing action.

This is a strong, simply constructed trap for removing condensate from fixtures, steam lines, separators, laundry equipment, heaters, vulcanizers, dry kilns and other industrial apparatus where high pressure steam is used. It is the speediest and most powerful trap of its size and type made. This is due mainly to the shape of the Dunham bucket, as described under illustration.

Another big feature is its accessibility. The cap may be removed without disturbing piping connections. This exposes the double-end valve and reversible valve seat which are made of monel metal. These vital working parts may be quickly reversed or replaced. Compare Type 80 with any other trap for operating efficiency and durability.

Write to us to-day for complete information and price list on Dunham Traps and other heating and industrial specialties.

HUNTING TROUBLE

(Continued from page 32)

was very dirty, carrying small pieces of scale, etc. The trouble was obviously an obstruction in the 1½ in. feed pipe somewhere.

A Suggestion

Here is a good place to make a suggestion. When covering pipe it is very easy to mark where the unions are with a band of red paint. This will save much time and trouble sometime when it is necessary to disconnect for any reason.

It was finally decided to start with the elbow under the box, where the line turned to go up into the box, cut the covering back about 6 inches from the ell on each side and remove the cork, then cut through the ell with hacksaw (malleable fittings had been used so they could not be broken) unscrew the halves from pipe, and the line would be open for inspection.

The writer happened to notice the flexible coupling between the pump and motor when it started and thought it revolved in the wrong direction. The pump was stopped and it was found to be running backwards. On reversing the motor it gave all the brine wanted and the trouble was cured.

The real cause of the trouble was that an exhaust fan had been put in the kitchen and the motor cut into the lines, supplying the pump motor. The electrician carelessly reversed the pump motor in making the change. The pump was in a rather dark corner and ran just smooth enough, so it was almost impossible to determine the direction of rotation at full speed. The starting box was not located close to the pump and the person who threw in the pump could not observe it.

The trouble did not develop for a few days after the fan was put in, as the boxes held up themselves for a time and no one connected the exhaust fan with the brine trouble.

There is a moral to this. Always have a pressure gauge on discharge of pump. If there had been a pressure gauge on this line it would have shown something wrong with the pump at once, and the trouble would probably have been found easily—JOHN DAVIS, Toronto, Ont.

HIGH VACUUM BENEFITS

(Continued from page 22)

dimensions require to be varied for every different set of working conditions. The introduction of new types of jet and diffuser has made it possible to adjust the dimensions of the jet and the diffuser to suit all conditions, while still maintaining standard parts.

In fact, it is possible to adjust the expansion of the steam in the jet, to give the best possible results under any given working conditions, while the ejector is in operation, a feature hitherto impossible.

Ejector With Diffuser

A two stage ejector constructed on this principle is shown in Fig. 7. Live steam enters through stop valve A^1 connected to first and second stage nozzles B and C. The small valve A^1 is for the purpose of shutting off the first stage at starting until a vacuum of 25 inches is obtained in the second stage.

The steam expands in the nozzles and entrains the air and vapors entering through the suction branch D. The mixture of steam and air passes down through the diffuser E and is discharged through the passages F to the suction chambers G off the second stage, the absolute pressure of the mixture having been raised several inches of mercury.

The remainder of the steam entering at A passes through the second stage nozzle C which is designed to have a constant throat area, with a variable ratio of expansion, thus securing a constant steam supply. The variation of the ratio of expansion is accomplished by the adjustment of the position of the nozzle point H. This adjustment can be made while the ejector is in operation by means of the extension of the point which projects from the casing at K. The steam issuing at J from the nozzle C in the form of an annular sheet, having a very large surface compared with the weight of steam passing, entrains the mixture coming in through the suction chambers G and compresses it in the annular diffuser I to atmospheric pressure.

The whole then passes into the discharge belt M and is exhausted to atmosphere through the opening N.

Progress in New Power Equipment

AN AIR PREHEATER

A costly source of loss in connection with steam boiler operation is the quantity of heat carried away to waste by the flue gases. The days have long passed in which a high exit temperature of the gases was tolerated for the sake of producing natural draught and economizers are fitted in all plants of any importance in order to utilize as far as possible the heat which the boiler itself cannot extract from the gases.

The close regulation of the excess air supply to the fires which is rendered possible by the use of CO_2 recorders has had its natural effect in increasing the temperature of the exit gases, and this again has called attention to the amount of recoverable heat which these gases contain. In addition to extracting a part of this heat by means of economizers, or indeed as an alternative to the use of economizers, it has often been proposed to use the heat of the waste gases to raise the temperature of the air supplied to the fires.

Up to the present, there are two ways by which it has generally been attempted to raise the temperature of air for combustion. In steel works' furnaces, a common practice is to pass the fresh air and the flue gases alternately through regenerating chambers, so that the incoming air picks up heat from high temperature from the passage of the brickwork previously raised to a the flue gases. For boiler furnaces the flue gas temperature is not sufficiently high to make this plan practicable, quite apart from the difficulty of carrying it out. Hence when regeneration has been applied to steam boiler plants it has been customary to transmit the heat from the waste gases to the incoming air, through metallic surfaces separating the air passages from the flues.

Heat transmission under such circumstances is not very effective, as the temperature difference is not great and the surfaces of the heating device are prone to become covered with a layer of soot or tarry matter which acts as a nonconductor.

A third solution has now been evolved in the form of an air preheater, designed by Frederick Ljungstrom of Stockholm, Sweden, whose fertility of mind has been demonstrated by the Ljungstrom Steam Turbine and Turbo-Locomotive.

Fan Supplies Air

Referring to the diagrammatic figure, fresh air is drawn by a fan into the upper portion of the casing, which is divided into two parts by a vertical partition. The air is confined to one side of the partition and passes downwards to a similar semi-circular chamber, through the body of a porous cylindrical drum or rotor.

The flue gases from the boiler traverse the apparatus in the reverse way, entering the lower semi-circular chamber and passing upwards through the rotor to the upper chamber, whence they are exhausted and impelled to the stack by another fan.

The integral fans are carried on a common shaft and the required speed of the rotor—about six revolutions a minute—is obtained by means of suitable gearing connecting the fan shaft with the driving roller.

The rotor is kept in a state of continual slow rotation so that the part heated by the flue gases is continually passing to the other side of the device and gives up its heat to the cold air sweeping through it. Similarly, of course, the cooled part of the rotor is continually returning to be reheated by the flue gases.

Cleaned by Jet

It will be observed that there is no transference of heat through metal in the process. A deposit of soot or tarry matter does not therefore have any very serious effect upon the action of the apparatus, which moreover may be cleaned in a few moments by means of a steam jet.

The rotor is built of thin sheet steel and divided into sections by radial plates, which serve as stiffening spokes. In each section the heating elements are placed concentrically. These consist of specially corrugated plates alternating with plain, thus forming, when assembled, a great number of passages and resembling a honey-comb structure. It will be appreciated that this design allows a very liberal heating surface to be provided in a heater of comparatively small dimensions and with very little obstruction to the passage of the gases and air.

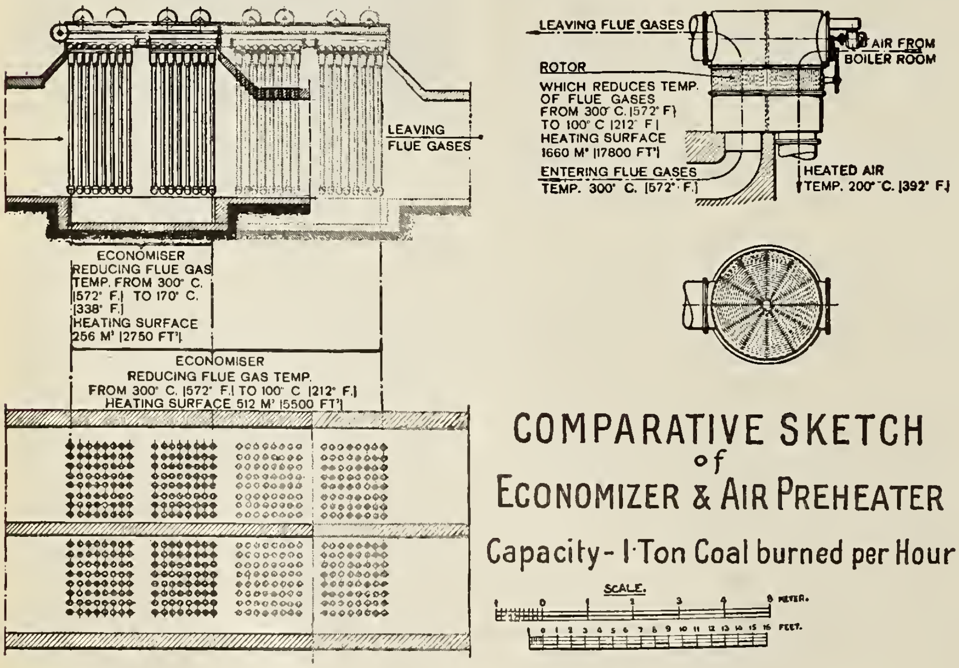
On the outside of the rotor a heavy steel ring is fastened, against which the carrying and guide rollers are working. As the rollers carrying the weight of the rotor are mounted on ball bearings, the amount of power required for driving purposes is insignificant.

Incidentally as friction drive is employed, this precludes the possibility of trouble resulting from contraction or expansion.

It is claimed that as an alternative to an economizer, the Ljungstrom Air Preheater is not only more efficient, but lighter and less expensive in first cost and maintenance.

Figure 1 shows an air preheater designed to deal with the flue gases from a steam plant burning one ton of coal per hour, as compared with an economizer of standard design intended for the same duty. In both cases it has been assumed that the temperature of the flue gases leaving the boiler is 572 degrees Fahr. The air preheater cools the flue gases down to about 212 degrees Fahr., thus absorbing the heat between these limits which, according to tests, results in a saving of fuel of 20.1%. The weight of the heating elements is 7,100 lbs.

The makers of the Ljungstrom Air Preheater are James Howden & Co., of America, Inc., Wellsville, N.Y.



LEAVING FLUE GASES
ECONOMISER REDUCING FLUE GAS TEMP. FROM 300° C. (572° F.) TO 170° C. (338° F.) HEATING SURFACE 256 M² (2750 FT²)
ECONOMISER REDUCING FLUE GAS TEMP. FROM 300° C. (572° F.) TO 100° C (212° F.) HEATING SURFACE 512 M² (5500 FT²)
LEAVING FLUE GASES
AIR FROM BOILER ROOM
ROTOR WHICH REDUCES TEMP. OF FLUE GASES FROM 300° C. (572° F) TO 100° C (212° F) HEATING SURFACE 1660 M² (17800 FT²)

REFINITE
RIVAL OF THE CLOUDS
TRADE MARK

Nature's Water Softener
Copyright 1920—The Refinite Co.

For Boiler Feed Water

Refinite makes scale impossible. It takes out the scale-forming lime and magnesia before the water enters the boilers. You save not only fuel, but the trouble, time and expense of washing boilers and replacing tubes.

A coating of scale even 1-50 in. thickness wastes 100 lbs. from every ton of coal fired.

Write for Information and Catalogue.

No. 146 N. 7th St., PHILADELPHIA, Pa.

The Simplest and best cleaner on the market is

PILLEY'S

Combination Flue Brush and Scraper.
Guaranteed not to break or the wires to pull out or lay over. A simple turn of the hand adjusts it to the tube, and the brush removes what the scraper loosens.
For sale by leading Canadian jobbers.
Manufactured by
PILLEY PACKING AND FLUE BRUSH MFG. CO.

A Reasonable Saving of 5 to 10%

Should You Expect More?

WE GUARANTEE that with the use of CYCLONE SHAKING AND DUMPING GRATE any grade of hard or soft coal, or screenings of same, can be burned with excellent results both as regards Economy and Capacity; that the total annual expense to the user for coal, interest, depreciation, repairs, damage to boiler, liability of shut-down, etc., will be much less than would be the case with any other type of Grate or Stoker on the market.

BETSON'S
TRADE MARK
PLASTIC FIRE BRICK

IDEAL for repairing furnace linings and arches or laying up complete linings and arches in one solid seamless piece and for making gas-tight baffles at any angle. No special forms, tools or skill required. Any good workman can do it.

Shipped plastic in barrels ready for use or dry ready to add water, from nearest warehouse.

Send for instructive booklet on furnace linings and baffles.

MONCRIEFF'S "UNIFIC" WATER GAUGE GLASSES

Moncrieff's "Unific" is not a cheap glass. But because it outlasts many ordinary glasses the "Unific" is economical. British Made.

JOHN MONCRIEFF LIMITED
PERTH, SCOTLAND

The "Unific" does not readily corrode. It resists extreme changes of temperature and withstands the highest working steam pressure.

Ends Cinder Nuisance

The Sturtevant Cindervane Fan effectually ends the cinder nuisance, at the same time affording excellent induced draft.

Ask for Folder 609.

B. F. Sturtevant Co.
of Canada, Ltd.
Montreal Galt Winnipeg Toronto

The reason the champion is always the favorite is because he's better advertised.

POSITIONS WANTED

FACTORY SUPERINTENDENT—OR CHIEF Engineer is open for engagement. Have had wide experience in operating power plants and handling help in Canada. Apply Box 107, Power House.

ENGINEER, SECOND CLASS CERTIFICATE for Ontario, wants permanent position. Has had good all-round experience. Apply Box 111, Power House.

FOR SALE

SELF-OILING HIGH SPEED ENGINE, SINGLE cylinder, 17 in. bore x 16 in stroke. Engine develops 200 H.P. when running at 235 R.P.M. with 100 lbs. steam pressure. There are two heavy leather belts 18 in. wide. The engine has two fly-wheels, each 78 in. diameter x 18 in. face. Apply Box 112, Power House.

BUSINESS CHANCES

SMALL BOILER REPAIR BUSINESS FOR SALE—with house property adjoining. No opposition. Located in a large manufacturing city. Reason for selling, owner in ill-health. Apply Box 110, Power House.

CONSULTING
& APPRAISAL
ENGINEER

Room 301—205 St. James St.
Telephone Main 6737. Montreal.

Every Engineer, Mechanic and Electrical Worker will welcome this new master set. It will answer your problems.

It will help you with your daily work.—A sure source of advancement and higher pay. Complete up-to-date information that is thoroughly and easily explained on every branch of modern engineering and electrical practice.

AUDEL'S ENGINEERS & MECHANICS GUIDES

4750 PAGES $1 A MONTH
8754 ILLUSTRATIONS $12 COMPLETE

These Guides tell you all about—

Theory, Practice and Operation of ALL Steam Engines; UNIFLOW and POPPET VALVE ENGINES, and LOCOMOBILES. Locomotive-Marine Engines; Turbines; Rotary Engines --the Indicator -- Lubrication -- PRACTICAL MANAGEMENT. GAS, GAS ENGINES--*Aeroplanes* and *Aviation*--HOW TO SELECT AN ENGINE. STEAM ENGINE rules and formulae. Steam Boilers; Heat-Combustion; Fuel and Flue Gas Analysis-C02 Recorders-Construction of all types of Boilers.--Mechanica Stockers--Oil Burners--Setting--Chimneys--Mechanical Draught --HOW TO SELECT A BOILER--BOILER DESIGN based on A.S.M.E. BOILER CODE--OPERATION FIRING. Pipes, Fittings--Heating and Ventilation--Refrigeration--Cooling Towers --Condensers--Distilling Apparatus--Elevators--Cranes--Ropes and Cables--Splicing--*Practical Electrical Engineering* as an aid for engineers and electricians in obtaining a license--ready reference index, covering entire field of Modern Electricity.

SHIPPED TO YOU FREE

Not a cent to pay until you see the books. No obligation to pay unless you are satisfied. Send coupon now--today and get this new master set for engineers. Pay only $1 a month.

SEND NO MONEY

THEO. AUDEL & CO.,
72 Fifth Ave., N. Y.

Please submit me for approval, AUDEL'S $10,000 MASTER SET FOR ENGINEERS & MECHANICS. Ship at once prepaid, the 8 numbers. If satisfactory, I agree to send you $1 within 7 days and to mail you , 1 monthly until $12 is paid.

Stephen's Boiler Feedwater Treatment

Don't endanger your boilers with old-fashioned, expensive methods which are often ineffective. You'll find that the Stephen's Feedwater Treatment is not only more economical but ensures the removal of old scale and prevents the formation of new scale in absolute safety.

Consult our engineers. They are always happy to discuss your feedwater problems in a practical way without obligation to you.

TRIPLEX DRAFT GAUGE

Gives you accurate knowledge of furnace conditions at a glance. It indicates pressure in wind box, draft in furnace above the fire and draft in last pass.

It is designed and built for convenience of installation, maximum visibility and permanent accuracy. Each instrument must pass the Foxboro quality test.

Write for Bulletin CF-131.

PACKINGS

THE GARLOCK PACKING COMPANY

Dust-Destroyer and Thief!

The Trumbull Cliffs Furnace Company, of Warren, Ohio, U.S.A., pay no tribute to dust! Their turbo generator cooling air is filtered in this 25,000 cu. ft. per minute Midwest Installation.

Dust in the cooling air for your generators, motors and transformers, not only threatens you with short circuits, fires, and serious damage, but as it accumulates in the air passages and windings, it robs you of machine capacity. Don't pay tribute to dust! Keep cooling air absolutely clean with Midwest Air Filters. They have no moving parts—no sprays—nothing to get out of order. And maintenance costs are practically nil!

WRITE DEPT. F-15 FOR OUR NEW DATA BOOK.

MIDWEST AIR FILTERS

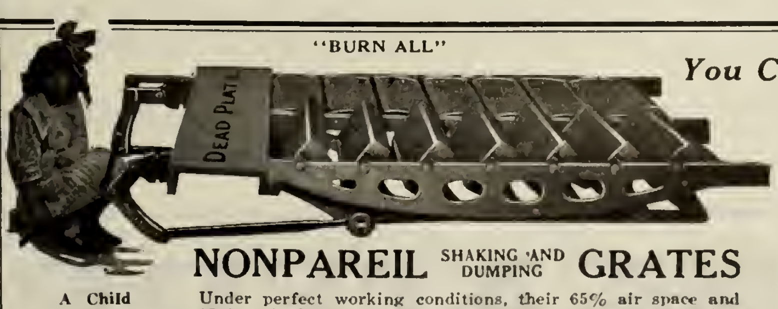
MIDWEST CANADA LIMITED
83 Craig St. W., Montreal, Que.

DOMINION BELTING CO. LIMITED
HAMILTON - CANADA
Quebec Branch, 51 Duluth Bldg., Montreal

Sole Manufacturers:

"Maple Leaf" Brand Stitched Cotton
Duck Belting, Belt and Dressing

The demand for our products has steadily increased because the standard of quality has been strictly maintained. We make only one grade, the best that can be produced. Write for prices and further information.



NONPAREIL SHAKING AND DUMPING GRATES

A Child Can Operate It.

Under perfect working conditions, their 65% air space and 95% underdraft is cutting fuel bills by 10%. SEXTON has installed them in a number of leading Canadian plants. Get a line on them today and be convinced.

You Can See

SEXTON'S
FIREBRICK WORK

In many of the largest plants in Canada. Using only the best High Tension Fire Cement, he handles the work RIGHT—and without waste of time. That's why it lasts longer and gives 100% satisfaction.

Whether it's building-in boilers, general repair work (renewals and repairs for all kinds of shaking and dumping grates)—see SEXTON first.

Anti-Clinker
SHELL-BAR GRATE BARS

Designed and built by men with practical experience, the Shell-Bar Anti-Clinker Grate Bars are built to

Get the last bit of heat out of the last bit of fuel

Maximum air space permits perfect combustion even of low-grade fuel. Nothing is burnt to waste—nothing is wasted in clinkers. Wherever they are used they are giving more heat with less fuel.

Some of the Advantages of the Jeffrey Standard Scraper Conveyor

Simplicity—It does not consist of much machinery and does not require much wood or steel for support.

With timber supports it may be quickly installed as a temporary or permanent equipment in power house extensions.

Can be readily inspected. Consists of no complicated parts either in steel chains or its Scrapers.

Wide range of Service from one conveyor. May be installed on the horizontal, on an incline, or as a combination in one conveyor of both horizontal and incline or two inclines, with the joining connection between the horizontal and incline or the two inclines being made in a curve of large radius.

Low upkeep and ease of repair.

The J. M. T. Reducing Valve

"Every installation is a demonstration of merit"

Since the introduction of this J.M.T. Valve there has been no "problem" of pressure reduction of air and steam. A sudden change in the low pressure demand, or variations in flow and pressure on the high pressure side, have no effect on the constant low pressure maintenance.

The Morrison catalogues give full particulars of this and the other Morrison Steam Goods. Have you a copy?

YOU HAVE TO DECIDE
Between Long Service and Low First Cost When You Buy a Rod Packing.

Reason will tell you that a packing that will stand up and give long service under high pressure, superheated steam, and compressed air, must be made of materials that are not cheap.

To meet the exacting conditions a rod packing must be made of the best materials obtainable.

YOU CANNOT AFFORD TO TAKE CHANCES.

IT IS A WELL KNOWN FACT THAT

TRADE MARK

"PALMETTO" PACKING

will outlast other packings because it is made of materials usually considered too good for packing. It is thoroughly lubricated in each single strand before braiding, and not superficially lubricated like other packings.

If you don't know that "Palmetto" gives longer service than other packings then let us send you at our expense working samples to test under your own conditions.

Which Stoker?

-You Make this Decision Once-It Must be Right

EXPERIMENT with any equipment is costly — but experiment with mechanical stokers is out of the question. The investment is large; it is made once in a lifetime; snap judgment won't do—*which stoker?*

Canadian plants want greater boiler capacity—continuous power day and night when necessary—they want this accompanied by greater economy in burning Canadian coals and by lower labor costs.

This means *high-duty stoker firing*, best exemplified by the "Jones A-C" (Automatic-Cleaning) Stoker.

Regardless of the size of the plant, the grade of coal burned or the local conditions to be met, the logical, safe answer to "*which stoker?*" is "Jones A-C."

The new "A-C" catalog goes into detail. "Jones" engineers, with unmatched experience in this specialized field, will gladly make a survey of your plant and give you the full benefit of the best they have learned in installing stokers in many prominent power houses. Investigation implies no obligation.

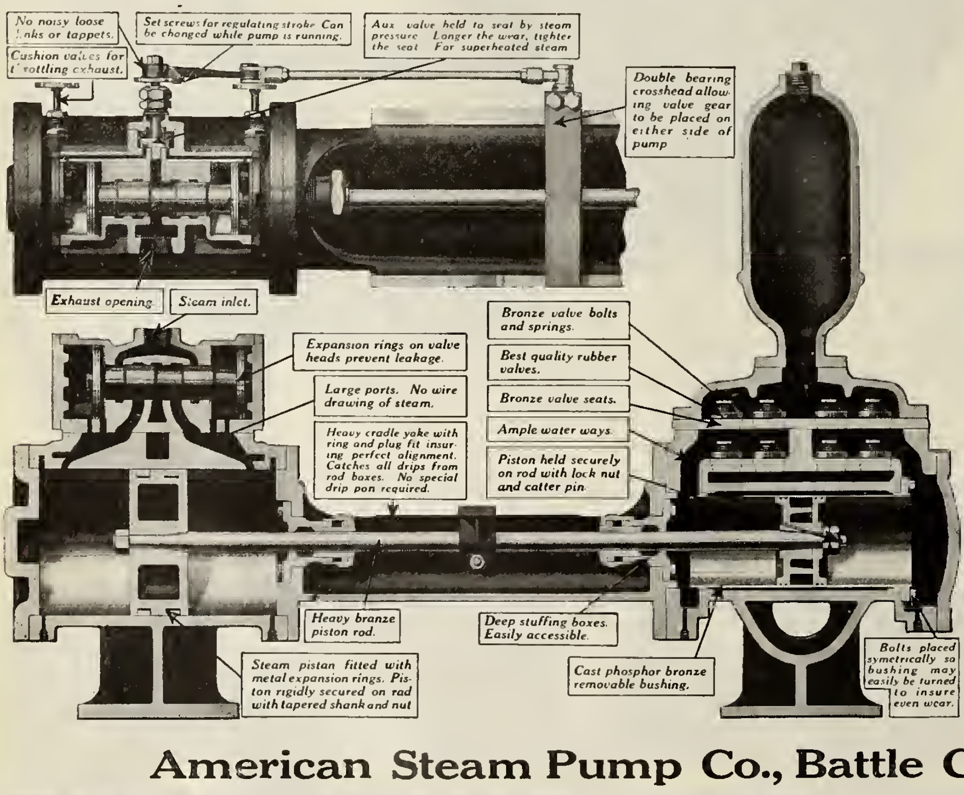
AMERICAN--MARSH PUMPS



No noisy loose links or tappets.
Set screws for regulating stroke Can be changed while pump is running.
Aux valve held to seat by steam pressure Longer the wear, tighter the seat For superheated steam
Cushion valves for throttling exhaust.
Double bearing crosshead allowing valve gear to be placed on either side of pump
Exhaust opening.
Steam inlet.
Bronze valve bolts and springs.
Expansion rings on valve heads prevent leakage.
Best quality rubber valves.
Large ports. No wire drawing of steam.
Bronze valve seats.
Heavy cradle yoke with ring and plug fit insuring perfect alignment. Catches all drips from rod boxes. No special drip pan required.
Ample water ways.
Piston held securely on rod with lock nut and cotter pin.
Heavy bronze piston rod.
Deep stuffing boxes. Easily accessible.
Steam piston fitted with metal expansion rings. Piston rigidly secured on rod with tapered shank and nut
Cast phosphor bronze removable bushing.
Bolts placed symetrically so bushing may easily be turned to insure even wear.

THE illustration tells its own story. Why the American-Marsh are the most reliable, trouble-proof and efficient pumps on the market.

Less than one-half the wearing parts found in the duplex type while a saving of 25% in steam consumption is guaranteed.

Over 160,000 in successful operation.

Ask for catalog.

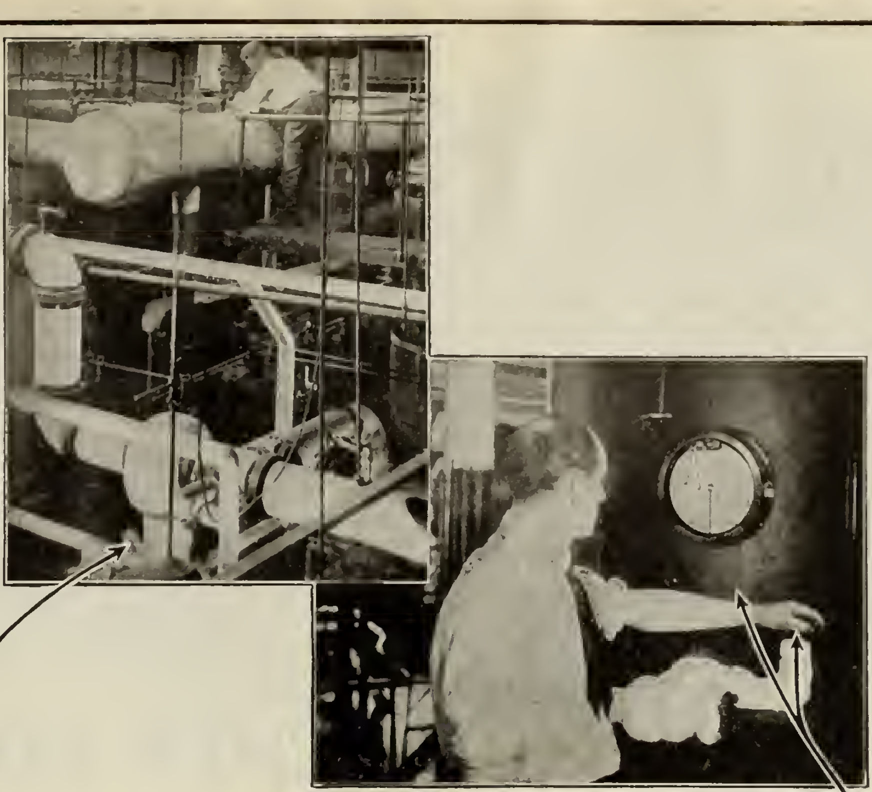
American Steam Pump Co., Battle Creek, Mich.



This hand tells the story

To regulate this brine cooler. they had to journey from the control valve (shown by the arrows) to a thermometer behind some pipes at the back of the cooler, then up a ladder at the far end of the room to the thermometer atop the cooler and from there back to the valve—and after setting the valve the only way to tell whether it was right was to make the trip again.

Some job!—and, naturally, the operators preferred guesswork to footwork and control was far from perfect.

With a Foxboro Long Distance Two-Pen Recording Thermometer installed, accurate control becomes at once a matter of course.

From 40 to 90 minutes a day are saved by using the one recorder. The time saved plus the improvement in cooler operation pays for the installation many times over.

The operator has an accurate, continuous record of both incoming and outgoing brine temperatures. He can determine cooling effect at a glance and adjust the valve accordingly. The superintendent has a permanent record of cooler operation.

The bulbs of the Foxboro Recording Thermometer can be placed 500 feet from the recorder case.

Check up the places in your plant where you can improve conditions and save money by installing the Foxboro Long Distance Recording Thermometer.

For places where you need a single temperature indication, without a record, the Foxboro Long Distance Dial Type Thermometer is accurate and easy to read—therefore often read.

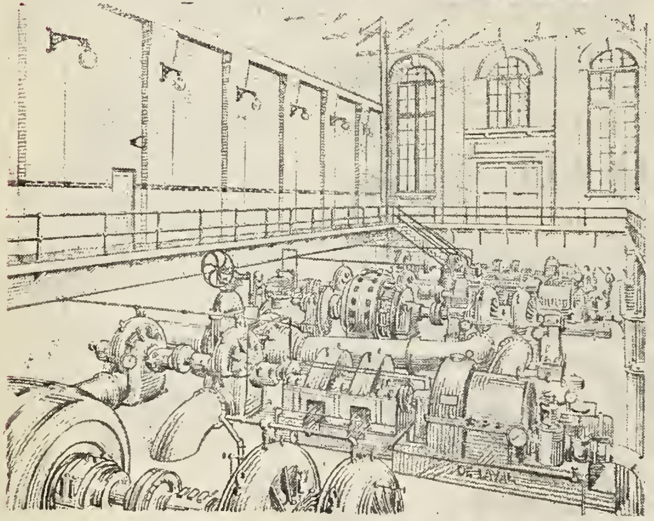
De Laval Pumping Equipment in Canada



THE John Street Station of Toronto, here shown, has twice made new records for duty with its De Laval geared steam turbine driven centrifugal pumps. The remarkably high percentage of De Laval Centrifugal Pumps in installations using electric power throughout Canada, as at Toronto, Hamilton, Burlington, Montreal, Lindsay, Brockville, etc., is also evidence of the practical value which engineers attach to simplicity, durability, low power consumption, the power limiting characteristic and the low starting torque inherent in De Laval pumping units.

State your pumping conditions and ask for Special Publication W-100.

When you need a new Boiler, let this plant show you what it can do

With our 35 years' experience, we are able to turn out Boilers of all types at low first cost, of high efficiency and long service records, and with minimum stoppages for repairs.

The construction is carried out with scrupulous care at every step. All rivet holes are accurately laid out—no drift pins being used. Caulking edges are neatly bevelled and all seams thoroughly caulked. Tube holes in heads are accurately machine-cut and edges carefully chamfered. All tubes are expanded and beaded over at both ends. On completion all boilers are tested to at least one and a half times their working pressure before leaving our works.

We build to suit the Interprovincial Boiler Code and we can ship economically by rail or water. Let us show you what we can do for you.

We build Horizontal Return Tubular, Vertical Tubular, Locomotive Type and Marine Boilers. We construct Tanks, Penstocks and Steel Plate work of all kinds. We furnish gray iron and brass castings of any size in the rough or machined to order.

Traveling Water Screens

THE function of the Link-Belt Traveling Water Screen is to automatically remove all debris and rubbish from the water which passes through them. A steady supply of clean water to the condensers is thus assured at all times. They are self-cleaning and require little attention. Let us tell you more about them.

Link-Belt traveling water screens, as illustrated, were selected by Stone & Webster, Inc., Engineers and Builders of the new Hartford Electric Light Co. power plant, at Hartford, Conn.

The Link-Belt line includes complete coal and ashes handling equipment; elevators and conveyors, the Peck Carrier, locomotive and crawler cranes, electric hoists, portable loaders, skip hoists, drag scrapers, crushers, chutes, gates, weigh larries, coal bunkers, track hoppers, etc. Let our experienced engineers suggest better ways and means for handling your coal and ashes. Send for catalogs.

Diamond Specialty Limited, Windsor, Ont.

Yarway Blow-Off Valves have Given Willys-Overland Co. Excellent Service for 13 Years

In 1910 the Willys-Overland Company installed their first Yarway Seatless Blow-Off Valve, in the plant at Toledo, Ohio. They have sent in a number of repeat orders, the last one a few months ago. From the last report, these valves have given excellent results.

The Yarway Seatless Blow-Off Valve is built especially to withstand the destructive action of mud, grit and sediment under high pressure. It has no-seat-to-leak; therefore, it stays tight, keeps the water and steam where they belong, and saves fuel.

The Yarway Seatless and the Yarway Double-Tightening Valves in tandem, form the ideal combination for blow-off service, complying with boiler laws of every state.

We shall be glad to send you a copy of our Booklet B-410, in which both valves are fully described—write for it.

A Jenkins Disc is quickly renewed

without removing the valve from the line

A JENKINS Disc in a Jenkins Valve is the right combination—a tight-closing valve is assured. The disc has very long life, and, when necessary, it can be quickly renewed with the valve left in the line.

The compositions of the various Jenkins Discs are the result of constant study and 58 years' experience in disc manufacture. Each is exactly suited to the particular service for which it is intended. The schedule at the right gives the principal discs and their use.

Use the disc ONLY in the particular service for which it is recommended. If in doubt as to the kind of disc you need, let us know what work it is expected to do and, we will recommend the right one or prepare a special composition to suit your requirements.

A JENKINS VALVE fitted with a JENKINS DISC—
assurance of perfect valve performance.

Schedule of Principal Compounds and Service for Which Jenkins Discs are Guaranteed

NO. 119—This is the disc which is regularly used in all Jenkins Standard Globe, Angle, Cross, Y or Blow-off, Safety and Radiator Valves when intended for steam service. It is dark red in color. The composition is tough and flexible in service when under steam pressure. It shows remarkable freedom from cracking and flaking and unrivalled durability in working steam pressures up to 150 pounds.

No. 80—A disc of dark gray composition for steam service. It is extremely hard although sufficiently elastic under pressure to insure perfect tightness.

No. 110—A tough, semi-hard disc especially recommended for hot water service. This is the composition regularly used in Jenkins Check Valves, both standard and extra heavy, horizontal and swing patterns, when intended for boiler feed lines and returns.

No. 93—Rubber disc made expressly for cold water, gas or air service, and regularly supplied in all Jenkins Globe, Angle or Check Valves when intended for such service. This is a tough, pliable composition suitable for hydraulic pressures up to 350 pounds.

No. 94—A soft, tough, elastic disc for low pressures of water, gas or air. Suitable for use in valves or other devices where a tight closure is desired with a minimum amount of pressure applied to disc.

Nonpareil Cork Covering on brine lines at the City Hospital, Cleveland, Ohio

Put On In Sections

NONPAREIL Cork Covering comes to you ready to apply—36-inch split sections for pipes and molded jackets for fittings. Cement the joints, wire in place and paint. Simple, neat, and permanent. No troweling or wrapping. No messy waterproofing. Nonpareil Cork Covering is finished at the factory with moisture-proof mineral rubber.

Like Nonpareil Corkboard, Nonpareil Cork Covering is made of clean, dry granules of pure cork, compressed in molds and cemented with its natural gum—the most efficient low-temperature insulation known. Nonpareil Cork Covering prevents at least 80 per cent. of the refrigeration loss from uninsulated lines and the saving is usually enough to pay for the insulation in much less than a year.

And, best of all, it is permanent. Apply it properly in the first place, keep the wires tight, and paint it once a year, and Nonpareil Covering will last as long as the pipes.

Have you had the new booklet, "Permanent Covering for Refrigerated Lines and Tanks?" Write for a copy; it is sent free.

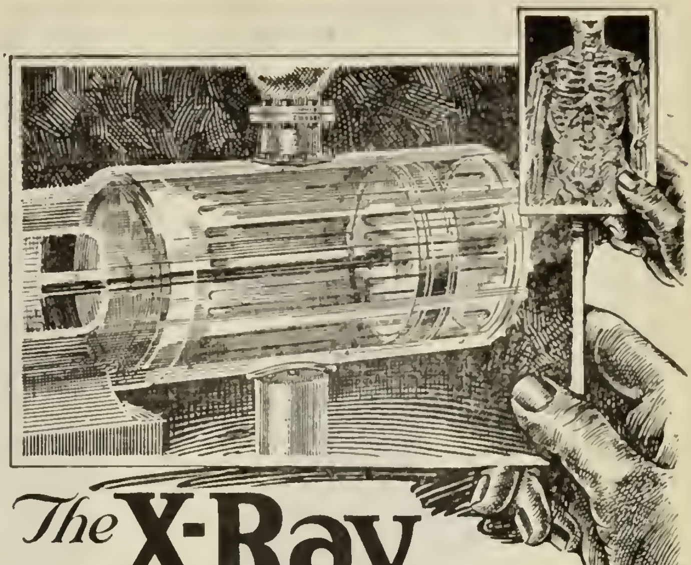
For All Cold Lines



The X-Ray of the Engine Room

How often you have said to yourself—"If I could only see what is going on inside of that engine I would find out in an instant what is wrong!"

But when you said this you didn't stop to think of the possibility of doing this very thing by using an

AMERICAN
THOMPSON
IMPROVED INDICATOR

By means of this sensitive instrument you can virtually look into your engine and locate internal troubles, just as the surgeon looks into the human body and ascertains the cause of certain disorders with the X-Ray. **The American Indicator is the X-Ray of the engine room.**

If a valve is leaking or improperly set, causing too much lead, late admission, too much compression, too early cut-off, late release, unequal cut-off, etc.—if your eccentric has slipped back or is too far ahead—if there is loss of steam pressure due to improper piping—the American Indicator shows it.

It gives the exact horsepower developed at every point of the stroke. A score or more of engine troubles are as clearly put before you by the American Indicator as though the internal workings of your engine were plainly visible.

Many features and refinements not found in other indicators render the American most accurate, durable and easy to use.

Our Catalog T-33 explains these features in detail. Write for a copy to-day.

The Reign of Electricity

WHEN men learned to liberate the energies of coal and use the power of steam as a motive force, the old world order passed away and the so-called "industrial revolution," a hundred years ago, ushered in the formative period of modern industry. The use of steam power opened the coal fields and later the oil wells, creating and developing transportation and industry as they are to-day.

Yet, although the possible expansion of industry is unlimited, the existing means of bringing to it energy, in the material form of coal, is daily becoming so difficult and costly that Central Canada at least must soon face once and for all, the problem of obtaining fuel within the borders of the Dominion, instead of depending upon the whims of American coal miners and operators.

It is certain that ever increasing costs and threatened shortages indicate that means must speedily be found of displacing the fuel imported from the United States at $16.50 a ton, whether the solution be in cutting the cost of transportation of coal mined in Alberta at $2 a ton; adequate facilities for coal storage or the reduction of coal to coke in the Maritime provinces at prices which will permit of effective competition in Ontario and Quebec markets.

In any event it is apparent that a fuller and more complete utilization of coal is imperative otherwise the coming decade will surely signal the end of the formative period of industry, and the untrammeled reign of the new motive force, electricity.

This force, virtually energy itself, has the capacity to to work freed from substantial form, devoid of bulk, practically abolishing time in its transmission and to a great extent distance, capable of subdivision and distribution, easy of application and adaptable to a vast range of utilization.

As a motive power, electricity was first applied to portable machinery and the locomotive, but now it has become the driver of numberless devices; in mines for pumps, ventilators, coal-cutters, drills, crushers and hoisting machines; in the iron and steel industry for refining steel and iron, making steel directly from the ore, welding, cutting metals, the electric motor replacing more and more the rolling engine; in textile, pulp and paper mills and mills of every description electricity is gradually replacing steam because of ease of handling; on the farm not only for machinery and irrigation, but even as a stimulant for increasing crops; in electro-chemistry it has limitless potentialities; in communication and in transportation its use is magical—in short although electricity, within the brief period since its advent as a practical factor has been put to such varied and extended usages, the incalculable realm and scope of its application are but beginning to be grasped.

Watching an Idea Grow

IT'S as good as a game of golf to watch an idea grow. You know how it is. You take something which seems to be almost nothing. You pass this something to a man who adds something else. Then he passes it to another, and after a while you have something that is a real, great big something.

Well, that's just what happened and the result of it will be spread before you in the October 20 issue of Power House. And some of the ablest men in the power plant field are sure this issue will make every engineer in Canada sit up and think!

* * * *

Controlling Air Supply

SEVERAL prominent engineers have voiced the opinion recently that maximum boiler efficiency will never be obtained until boiler rooms are enclosed in air-tight compartments and the air supply controlled just as rigorously as the quantities of water and fuel.

Until comparatively recently little thought was given to the air supply in the power plant, though it has long been recognized that this is a factor of great importance in gas producer practice, in which latter case, especially in pressure plants, fairly accurate control is actually maintained in daily operation.

Excess air is a very general cause of loss in boiler plants, sometimes amounting to 500 per cent. or more; it results not only in lowering furnace temperatures, thus decreasing radiant heat transmission, but also in carrying away vast quantities of heat in the chimney gases.

Even if the temperature of the latter be as low as 300 deg. Fahr. it is obvious that every pound of excess air sent out of the stack at that temperature has had to be heated uselessly from around 60 deg. Fahr. to that figure, a rise of 240 deg. Fahr.; this represents sheer loss except in so far as the greater volume of gas may enable the chimney to show a better efficiency. Unfortunately most stacks are none too large for their legitimate duty and the increased volume is doubly desirable.

Too little air results in poor furnace efficiency through incomplete combustion and heavy losses are possible with a comparatively small deficiency. There is, therefore, just one point at which maximum efficiency results and draught gauges, recorders and other apparatus are intended to assist the operator to find that point and keep close to it in continuous working. The exact amount of air required in excess of the theoretical quantity to oxidize the fuel depends upon various factors, amongst which the type of fuel and the form of the combustion chamber are two of the most important.

Modern practice leans heavily toward the use of preheated air and early fears that mechanical stokers could not stand the temperatures involved have proved groundless, there being numerous examples where air at 300 deg. Fahr. is being handled with no sign of trouble.

The air is heated by the flue gases either in conjunction with the use of water economizers, or instead of this method, it is possible by the combination of both means to reduce the chimney gases to about 300 deg. Fahr. in some cases when using fan draught, and not only is this heat conserved but the furnace conditions are materially improved, a larger proportion of radiant heat being available, with a higher initial furnace temperature.

Properties of Carbon Dioxide As a Refrigerant

By J. H. PRATT*

An Interesting Review of the Sources, Manufacture and Uses of This Odorless Gas in a Refrigerating Plant—Its Cost and the Operating Pressures Necessary

CARBON DIOXIDE is a colorless, odorless, tasteless gas, approximately one and one-half times heavier than air. It has the following characteristics:

Critical temperature.............88.6 F.
Critical pressure......1,078 lbs. per sq. in.
Boiling point at atmospheric pressure 110F.
Latent heat of vaporization at O F. 117.5 B.t.u.

This gas exists to a slight extent in the atmosphere; in country air, 0.3%, and in city air often as high as 0.6%. It is non-poisonous, but does not support respiration or fire, due to the exclusion of oxygen. Ordinary flame is extinguished by from 10% to 15% carbon dioxide, "but even 20% is not dangerous in an hour to animals, and probably not to man." The "pathological" effect of a small percentage of carbon dioxide is used by professors in establishing a new method of artificial respiration in gas poisoning cases.

Produced by Nature

Carbon dioxide is produced by nature, through all types of combustion, decay and fermentation, and is given off in large quantities by certain active volcanoes. Natural gas wells are found in Europe, and three have been found on the American continent.

The constant tendency to increase the percentage of carbon dioxide in the atmosphere through breathing, combustion, etc., is overcome by the chemical action of the chlorophyll, or green coloring matter of plant leaves, which absorb the carbon dioxide, releasing oxygen, and turning the carbon into plant structure. This property of carbon dioxide has been used in Germany, and is just being developed in America to increase the growth of plant life in green houses by the increase of carbon dioxide percentage in the atmosphere.

Scientists claim that the small percentage of carbon dioxide in the earth's atmosphere controls the temperature of the world, acting as the glass of a greenhouse, holding in the heat waves. They claim that, in prehistoric times, the carbon dioxide percentage was twice as high as at present, and that this caused the heavy plant growth which produced the coal beds of to-day. They also state that halving the carbon dioxide percentage would reduce the temperature of the earth to that of the moon, with the consequent death of all vegetable and animal life.

Artificial Production

The artificial production of carbon dioxide amounts to between fifty and sixty million pounds annually. Part of this is recovered from natural mineral springs. Small quantities are made by breaking down magnesite ore, with a resulting by-product of Epsom salts. Other comparatively small quantities are reclaimed from the fermentation of molasses in industrial alcohol plants.

It is a pity that we cannot have, in every Canadian power plant, a prototype of the classic Dutch boy who stuffed his finger in the hole in the dyke and thus saved his country from inundation.

High cost of fuel and labor are sufficient handicaps to the economical production of power. But the other factors—the leaks through which steam escapes or through which valuable heat units are dissipated—these are things that any wide-awake engineer can prevent.

At least 90% of the carbon dioxide made to-day is manufactured by the so-called coke process. This consists of burning high-grade coke under specially constructed boilers, with carefully regulated draft, producing flue gases with 17% to 19% carbon dioxide. These gases are scrubbed free of mechanical dirt and sulphur compounds, and are then passed into large coke-filled absorbing towers where they meet a counter-current flow of lye solution, made up of sodium or potassium carbonates, dissolved in water.

The lye solution dissolves the carbon dioxide from the flue gases, is then circulated through a series of heaters, and finally pumped into an expeller or still, where it is boiled out by the condensation of the exhaust steam used by the engine which operates the plant.

Release Gas at Still

The gas released at the still or expeller contains a large quantity of steam which is removed in an atmospheric cooler. It then passes through a series of traps and separators, and is delivered direct to the low pressure suction of the liquefying compressor.

This compressor, operating against pressure ranging from 950 to 1,250 lbs., is built with three stages. In modern plants it is direct-connected to a specially designed steam engine, which also drives the circulating and cooling water pumps. Well designed plants are balanced so that there is just enough steam produced from the combustion of the coke to operate the machinery and compress the carbon dioxide from the flue gases.

Liquid Containers

Carbon dioxide is sold and shipped in two standard sizes of cylinders. The small one, containing 20 lbs. is 5 inches by 51 inches high, and the larger one, containing 50 lbs., is 8½ inches by 51 inches high. These cylinders have a wall approximately three-eighths of an inch thick to withstand the pressures which may run up to 1,300 to 1,400 lbs. per square inch, when exposed to the summer sun. These cylinders must be tested at least once in five years by a 3,000 pound hydraulic test.

Turnover on carbon dioxide drums is very slow, particularly in the refrigeration field, where they are often held by customers for many months. This low turnover is one of the biggest cost factors in the industry, as the drum investment is high; consequently, interest charges, depreciation and maintenance total as much as the actual manufacturing costs.

Uses of Carbon Dioxide

Approximately 90% of the carbon dioxide produced is used in the soft drink trade, either by the bottler of carbonated beverages, or direct by the soda fountain. Other food products uses consist in the leavening of bread, as a preservative for apples, grapes, grain and cereal products. Its use in place of air in the manufacture of ice cream, butter and other dairy products, is becoming prevalent, as it is sterile, reduces the destruction of vitamins through oxidation, and has other mechanical advantages.

The refrigeration industry to-day uses from one to one and a half million pounds annually, or approximately 2% of the entire production.

Carbon dioxide is generally used as a fire extinguisher for ships, electrical fires, telephone switchboards, and was recently used for extinguishing a very bad mine fire, nearly a quarter of a million pounds being consumed in this particular instance.

Has Varied Uses

It is used in the chemical industry as a base for the manufacture of salicylic acid and aspirin, and a a non-oxidizing agent in the rubber industry.

Physicians and beauty doctors use it as a local anaesthetic, and one large city uses it as a substitute for illuminating gas in the humane killing of animals.

Ordinary coke process carbon dioxide will analyze 99.5 to 99.8 pure, the impurities consisting of less than 1-10 of 1% water, and the balance air. In ordering carbon dioxide for refrigeration purposes the manufacturer should be advised, as cylinders returned from bottling shops contain varying quantities of water which are not always entirely removed for the ordinary trade. Refrigeration drums are carefully drained and dried, and the carbon dioxide can then be guaranteed to be practically anhydrous.

---

*Extracts from a paper presented by the author at a meeting of the Chicago section of the American Society of Refrigerating Engineers.

The refrigerating engineer, on receiving cylinders, can invert them for a few hours and blow off small amounts of water which may still be there. If he then wants to test the purity of the gas for air, it can be done very simply by absorbing the carbon dioxide in caustic by means of a simple apparatus which can be supplied at a small cost by most carbon dioxide manufacturers.

As a Refrigerating Agent

Carbon dioxide has been generally used as the common refrigerant in European countries for many years, and refrigerating units are now built by several American manufacturers in sizes ranging from one half ton to 250 tons capacity.

Due to the fact that carbon dioxide, in fairly large quantities, is not dangerous to plant or animal life, these systems are generally used in connection with hospitals, department stores, hotels and theatres, where slight traces of other refrigerants would be dangerous or disagreeable.

The entire charge of carbon dioxide from the ordinary refrigerating plant can be emptied into the engine room without danger, as the amount can run up as high as 10% to 15%, while ½% of other refrigerants in the air may be fatal. The fact that it is heavier than air keeps it in the engine room, where it is not obnoxious, whereas other lighter than air refrigerants escape through the upper stories of buildings.

Special safety devices, including outside vent pipes, are not required by city ordinance, as is true of other refrigerants. Besides its general use for purposes already mentioned, it is now becoming popular in connection with fur storage vaults, markets, delicatessen stores, and florists, where the escape of other rerigerants might injure merchandise.

Gas Chemically Inert

Carbon dioxide gas is absolutely inert and stable under all conditions. It never forms non-condensable gases which have to be vented from the system; nor can it form explosive mixtures, either inside the refrigerating system, or around it. This inert quality allows the use of babbitt, bronze, and in fact any metal for bearings or structural purposes throughout the plant. The use of copper coils in shell type condensers is an advantage, as the amount of cooling surface is reduced, as well as the space needed for the apparatus.

Any good grade of low "cold test" oil may be used in connection with carbon dioxide refrigerating plants, as it has no chemical or emulsifying effects on oils, the life of this oil being practically indefinite, except as it picks up dirt and foreign matter in the course of operation.

Cost and Supply

Carbon dioxide at the present time is sold for refrigerating purposes at costs varying from 8c to 12c in different parts of the country. It can be purchased in reasonable quantities in practically every fair-sized city in Canada, as every soft drink bottler is a jobber of carbon dioxide.

Many new industries, such as the manufacture of helium; chlorine; oxygen and nitrogen as manufactured from liquid air, require extremely low temperatures, and have to turn to carbon dioxide as the agent.

A much smaller volume of carbon dioxide is handled per unit of refrigeration than required by any other ordinary medium.

COMPARISON OF REFRIGERANTS

	Refrig'n. (net) per lb. at 0° F. boiling temp.	Specific vol. of dry saturated vapor at 0° F.	Theoret vol. of piston disp't. for 100,000 B.t.u. refrig n.	Column three taking CO_2 as unity.	Suc. pres. lbs. per sq in. gage.	Condenser pres. lbs. per sq. in. gage.
Ethyl chloride	160.6	19.0	11,900	32.50	—10	8.2
Sulphur dioxide	149.34	7.49	5,020	13.72	— 4.35	45
Ammonia	491.1	9.114	1,855	5.07	15.7	126
Carbon dioxide	77.0	0.282	366.0	1	288	891

Note:—Refrigeration is a 0° F. Temperature at expansion valve 70° F.

From the table it is seen that the equivalent volumes for other refrigerants are six times greater for ammonia, fourteen times for sulphur dioxide, and thirty times for ethyl chloride. Unfortunately this is not quite as great an advantage as it first seems, as it is considered good practice to use long stroke compressors for handling carbon dioxide; consequently, the frame, fly wheels and other principal parts are ordinarily about the same size as used for ammonia.

Operating Pressures

The main argument used against carbon dioxide has been the comparatively high operating pressures. These ordinarily range from 250 lbs. suction to 900 lbs. condenser pressures. While these are high as compared to ordinary steam work, they are not excessive as compared to Diesel engine and liquid air practice.

With present-day construction methods, there is no real difficulty in handling these pressures. The elimination of fittings by the use of welded joints and bent pipe overcomes most of the trouble, although satisfactory flanged joints are easily made by experienced engineers. It is, however, considered good practice to cut down the amount of direct expansion piping as far as possible, in order to avoid joints.

Stuffing box leakage at these high pressures is often considered serious, but the writer personally investigated several five-ton machines recently that had operated with a loss of less than 50 lbs. of carbon dioxide per year.

In connection with the high pressures, it is not often understood that the pressure ratio, i.e., condenser pressure, divided by suction pressure, is much less for carbon dioxide than for ordinary air compressors, or other refrigerating systems. For carbon dioxide the range is from two to three, as compared to six to ten for ammonia. This low ratio gives maximum compressor economy, due to the small amount of clearance, re-expansion, smaller superheating losses, and much less piston leakage and valve wire drawing.

The critical temperature of carbon dioxide being 88.4 degrees F., it is a common fallacy that there is practically no refrigerating effect with condenser temperatures above this. The fact is, that carbon dioxide is not a perfect gas around the critical point, and there is no sudden change in properties in passing from 88 degrees to 89 degrees F.

Authorities do not agree whether the refrigerating effect is due to the liquefying of part of the gas through the expansion of the balance, or entirely to the effect of the high specific heat of the gas at this point. The fact is that the efficiency and capacity of the system are considerably higher than for a dense air machine under similar conditions.

Practically all British ships, and United States navy vessels operate such systems satisfactorily in equatorial waters, although the capacity of their plants is reduced as much as 50%, as compared to the usual 70 degrees F. condenser temperatures.

Simplicity of Operation

Due to the fact that cylinders, stuffing boxes and other compressor details must be well designed and built, and that high pressure piping must be heavier than for other refrigerants, the first cost of the ordinary carbon dioxide refrigerating plant is somewhat higher than others.

There is one exception to this in connection with the air cooling of theatres, where, due to the safety feature of carbon dioxide, it is possible to cool the air with direct-expansion coils, instead of using brine piping, as required by other refrigerants, where a slight leakage would render the entire ventilating system obnoxious. This saving in brine piping somewhat more than offsets the additional cost of the balance of the system.

Efficiency Tests

Unfortunately there are no good tests on record for larger carbon dioxide refrigerating plants, although it is understood that some are now being made, and that preliminary results show the general efficiency of carbon dioxide systems to be exactly as good as others.

Macintire states that "contrary to the expectation of most engineers the power required by the different refrigerating machines per unit of refrigeration is about the same. In fact, ammonia leads slightly in this respect, but the net result is so close that the matter of the horsepower per ton of refrigeration for usual operating conditions need not be considered when deciding on one or the other refrigerant."

Saving Energy With Electrically Heated Boilers

By F. JOHNSTONE TAYLOR

English Engineer Believes Future Developments Will Prove System Economical When Cheap Power Can be Purchased From Hydro Electric Plants

WHEN a plant depends upon electric power from an outside source the question of steam and hot water required for various purposes arises and this demand has usually to be met by an independent boiler.

Small coal-fired boilers are not, as a rule, economical, although in large industrial areas the gas-fired boiler may prove a satisfactory alternative if gas is obtainable at a favorable rate. Moreover, such boilers may be fired with producer-gas when this is available and, for that matter, blast furnace gas.

In districts, dependent upon electric power at low rates from hydro electric stations, there is the possibility of utilizing the current for generating the steam or heating the water required at a cost comparable with coal, gas, or oil, especially if these are costly, or difficult to obtain.

Electrically heated boilers are of late years quite an attractive proposition to the factory owner. High tension alternating current is essential with the modern types, because, except in the case of quite small units, resistances of the ordinary type are quite out of the question. Also the system of heating by induction is impracticable on account of the high cost of the apparatus.

The modern method is to fit the boilers with electrodes immersed in the water, which thus becomes the resistance for the current just in the same way as it is utilized when testing a generator. Voltages up to 8,000 have been successfully used and it is expected that much higher ones will prove practicable in the near future.

A Standard Type

A standard type of boiler is shown in Figure 1. Current is led from terminal A to electrode B, surrounded by tubes C, known as vaporizing tubes whose purpose is to increase the circulation along the electrodes. This is necessary to prevent steam bubbles accumulating on the electrodes and disturbing the whole resistance of the circuit. Moreover, the current flows from the electrodes through the upper and lower openings to the neutral point, that is the metal support on the end of the vaporizing tubes. By raising and lowering the tubes the path through the water from the electrodes to the neutral can be shortened or lengthened as required.

The conductivity is therefore increased or diminished and the heating effect controlled over a wide range.

Directing the current in the required direction prevents the liability of its passing direct from one electrode to the other. The tubes may be arranged for either hand adjustment or automatic.

Thus the current and the heating effect are kept constant, despite the change of temperature of the water. This of course entails a regulating device on account of the changing conductivity of the water with change in its temperature. The heating effect also rises as the temperature of the water rises, falling again when steam begins to form.

A horizontal boiler is shown in Figure 2, from which it will be seen that extension tubes A are fitted to the vaporizing tubes so as to render the water circulation effective in the lower part of the boiler. These tubes which are made of metal form the neutral point.

Factors in Success

Electric heating is specially suitable for making use of electric current which could not otherwise be employed and for using it during the night when obtainable at a cheap rate, but the correct method of applying the current and the best method of storing the heat energy are important factors in the success of an installation.

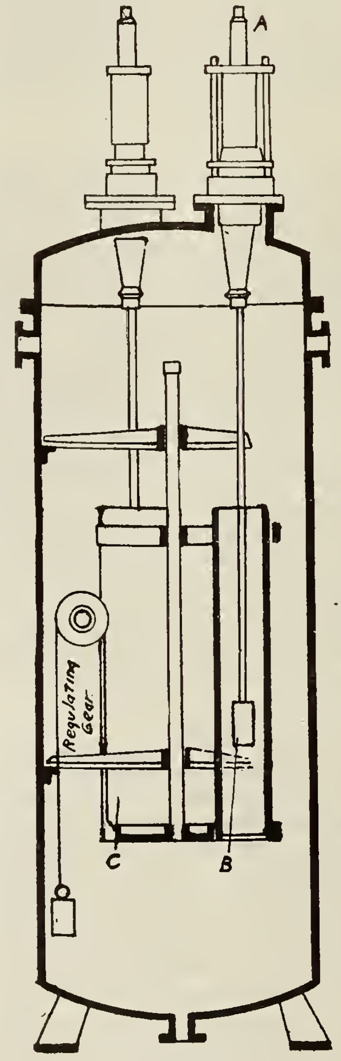

Fig. 1—Vertical boiler high voltage.

Countries with large hydro electric stations for instance have an excess of power at certain periods of the year and often a shortage at others. In consequence it may be good policy to use electric power for heating at one time and coal at another, and the expense of the dual installation may be warranted.

The heat accumulator may be constructed as a high pressure steam boiler and the steam drawn off from it for both heating and manufacturing processes. A boiler of this class could be heated up at a cheap rate during the night to a pressure of about 170 lbs. per square inch, the steam being drawn off during the day, although of course at a continuously decreasing pressure.

For manufacturing purposes, however, steam can be usefully employed at pressures down to about 28 lbs. per square inch.

The boiler must, therefore, be so designed that when it is at full pressure in the morning it can work till evening without the pressure falling lower than desired. Six to seven and a half lbs. of steam can be stored per cubic foot of hot water at the usual pressures and one k.w. hour gives about 2.7 lbs. of steam.

Presuming for a small plant there is some 80 k.w. available for ten hours during the night, the accumulator must be capable of storing 800 k.w. hours or approximately 2,200 lbs. of steam, corresponding to a capacity of about 350 cubic feet.

This is entirely dependent upon the cost of current, provided properly designed apparatus is installed, and the question as to whether it will prove cheaper than coal depends upon the cost of coal in the locality. It must always be remembered, however, that this system of electric heating is extremely convenient, demanding the minimum of attention and cutting out coal and ash handling. To bear a little extra cost for it may often be good policy, and if electric power is really cheap its use for this purpose is worth looking into.

Under working conditions experts claim that the same heating effect as 2.2 lbs. of coal are obtainable in small boilers with 3 k.w. hours; in large central heating boilers with 4 k.w. hours; in high pressure steam boilers with 5 k.w. hours.

A good example of this type of electric heating system is the installation at Spoerrie's spinning mills at Flums, Switzerland, of a boiler 51 feet 8 inches long by 6½ feet in diameter.

Water power drives the mills but conditions demand some of the water being let off at times when the mills are not working for the benefit of users lower down stream. This waste of energy is at times of low water utilized in an electrically heated storage boiler working from 55 lbs. in the morning to 15 lbs. in the evening. The load varies from 700 k.w. to 100 k.w., its average being 500 k.w. The current is three phase generated at 5,000 volts, 50 cycles. The boiler has a maximum water capacity of 10,000 gallons and a maximum pressure of 170 lbs. per square inch. Its storage capacity when discharging steam at 28 lbs. is 10,000 lbs. of steam. Owing to the short time it works with electric current the boiler has been highly rated.

There are in addition coal-fired boilers which bring the total storage capacity to 13,500 lbs. of steam. An auto bye-pass valve is fitted between the electric and the coal-fired boilers, which allows steam to pass from the former to the latter before the safety valve of the electric boiler comes into operation. The control apparatus between the two boilers consists of a switchboard with the necesrary instruments, servomotor control valves for the hydraulic regulator to regulate the current supplied to the electric boiler, control valves for the auto stop valves in the piping between the boilers, boiler feed pump and steam pressure reducing and distributing valves.

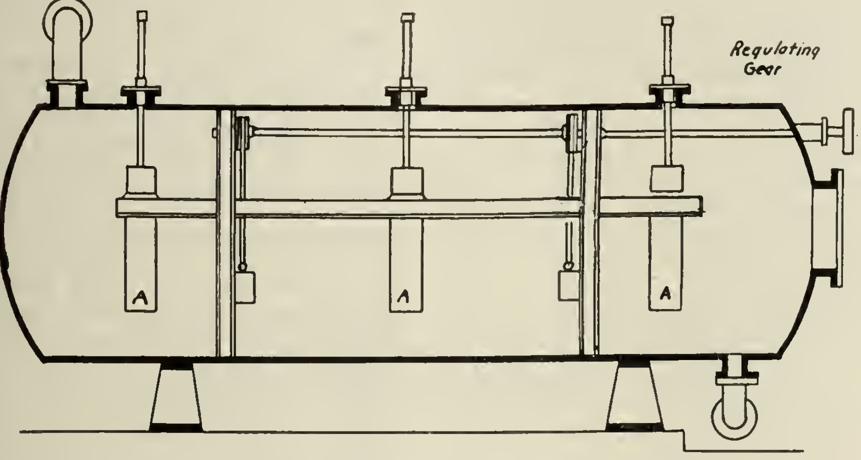

Fig 2—Horizontal electric boiler.

It is stated that the plant is in every way successful and that the combined arrangement, under the conditions prevailing is economical in working.

In fact there is no doubt that with the extended distribution of cheap electricity and a fuller appreciation of the necessity for the conservation of energy this system will receive more attention in the future.

Storage batteries cannot be charged from an alternating-current circuit without the use of a rectifier, of which there are a number of forms, such as mercury vapor, tungar, vibrating types, electrolytic, motor-generator sets (induction motor driving a direct-current generator), rotary converters, etc.

Inspire Exhibitors at Power Exposition

Directors to Award Certificates of Merit to Manufacturers With Attractive Booths at New York Show, December 3

THE importance of effective exhibits at the coming Exposition of Power and Mechanical Engineering in the United States is recognized by the management who plan to award certificates of merit to exhibitors who arrange their exhibits effectively.

The success or failure of an exhibitor may depend in great measure upon the arrangement of his exhibit. Obviously, excellent products may be shown to poor advantage and mediocre devices may be exhibited so that visitors will be attracted, will receive valuable information and may be moved to purchase. To inspire the arrangement of good exhibits the management offers these merit certificates.

December 3 to 8, 1923, are the dates set for the exposition and the place will be the Grand Central Palace, New York City. Contracts already signed give assurance that the event will exceed last year's, which was the first exposition of the kind in the United States, both in size and diversity. In addition to exhibits of devices for the generation of all kinds of power, space has been set aside for equipment used in the transmission of power. This will add greatly to the interest of the exposition.

Appeal to Engineers

The appeal of this exposition is to engineers not only in the power and mechanical fields but in all fields. Notable advances in the art and science of power generation will be packed in the Grand Central Palace and even the technical man, only casually interested in power, will find novelties to interest him for several hours.

The power man will delight in comparing competitive devices and in talking with the representatives of the exhibitors. He will become thoroughly acquainted with the entire field and will store information against the day when he has a troublesome problem requiring immediate solution when he will utilize the lore accumulated at the exposition.

The co-operation which the American Society of Mechanical Engineers is extending is an indication of the importance of the exposition. The A.S.M.E. annual meeting parallels the first four days of it, and to permit the mechanical engineers to reap the benefits of both meeting and exposition, the power and mechanical sessions at the meeting are to be assigned to the morning.

As the exposition does not open until noon each day there is no conflict and members can have ample time to give careful study to the exposition. The American Society of Refrigerating Engineers' meeting also parallels the first days of the exposition and members of that organization, as well as mechanical engineers, will be admitted on display of their badge.

Rising Fuel Costs

Rising fuel costs challenge the attention of all manufacturing executives and production engineers even though the power cost may be but a small percent. of the cost of finished product. Under present manufacturing conditions, the coal pile is an excellent place to start economy and the devices to be shown at the exposition are designed to effect that very thing. Furthermore, power is being used at a rapidly increasing rate and with the work of the world to be done mechanically, fuel must be consumed at a corresponding rate. So that not only is fuel economy made imperative by the demand for more economical use of fuel and heat but by a sense of duty to conserve fuel resources for future generations.

The managers of the exposition are Fred W. Payne and Charles F. Roth. They extend a hearty invitation to all Canadian manufacturers and engineers.

Recent Type H. boiler installations, made by the Goldie & McCulloch Co. Ltd., of Galt, Ont., include the Y. M. C. A., Kitchener, Ont.; Y. M. C. A., Galt, Ont.; Ottawa Collegiate Institute; Citizen Building, Ottawa; Rockcliffe School, Ottawa; La Corona Hotel, Montreal; Kitchener-Waterloo Collegiate; E. T. Coldrey, for Carleton County Court House, Ottawa; W. G. Edge, Limited, for Guelph Collegiate; G. Ruppel & Co., Kitchener; Dominion Shirt Co., Kitchener; The Hurlbut Co., Preston; Drake Avery Co., for G. C. I.; Wm. Knell & Co., for Waterloo School; Ottawa Auditorium; St. Andrew's Presbyterian Church, Ottawa; Garth Co., for Arnprior School and Ashbury College, Ottawa; Waterloo Lutheran Seminary; Newmarket High School; Ottawa Isolation Hospital; Tilsonburg Shoe Co., Limited; and L. N. Poulin, Ltd., Ottawa.

Operating a Vacuum System With a Steam Pump

By JAMES MACKAY

Power Used From High Pressure Boiler is Trifling, and the Pump, as a Matter of Fact, Acts as a Reducing Valve—Suction Eliminates Air From Radiators and Pipes

WHERE the boiler carries a pressure of more than twenty pounds, it is desirable, in the interest of economy, to operate a steam actuated pump for inducing a vacuum on the heating job. Where this is done, the power used by the pump is but trifling, and the pump, as a matter of fact, acts as a reducing valve, all of the steam being sent into the low-pressure side from the pump exhaust.

While the piping, valves, and specialties for a design such as this look complicated and expensive, as a matter of fact, the economy is considerable, and the apparatus is all of a reliable nature, and automatic in action. In a large building, with an extensive system of piping, a system of circulating the steam by means of a partial vacuum on the air lines, or return lines is practically a necessity, as without this aid, too great a pressure is necessary to force the air out of the system, and the time necessary to complete the circulation is too great.

Size of Cylinders

In determining the size of the cylinders of a steam operated vacuum pump, the area of the suction cylinder will depend on the speed of the pump and the amount of condensation and air it is to handle.

There are many formulae for working this out, for necessarily all need some modification, on account of allowances for inleakage of air into the system, and also to take care of the estimated "peak" load, when steam is first turned into the system in the early morning hours. These allowances are so many, and vary so widely that a purely empirical formula is now much used, which works out very well with the most complicated ones, based on friction losses, gallons of water per minute, and cubic feet of air per minute.

As the formula is used by some of the largest pump manufacturers and vacuum specialty manufacturers, it may be accepted as being safe and reliable, and has the very great advantage of simplicity.

To Find Capacity

To find capacity, in square feet of direct radiation, of vacuum pumps:

$$R = \frac{d\,d\,l\,n}{2}$$

Where
R = Square feet of radiation.
d = Diameter of water piston in inches.
l = Length of stroke in inches.
n = Number of strokes per minute.

As an example, a vacuum pump having a 10 inch diameter water cylinder with 12 inch stroke, and making 50 strokes per minute would be:

$10 \times 10 = 100$
$100 \times 12 = 1{,}200$
$1{,}200 \times 50 = 60{,}000$
$60{,}000 \div 2 = 30{,}000$, square feet of direct radiation as the capacity of the pump.

This would be the case, of course, without regard to the power used for operating the pump, whether line shaft, motor, or steam.

Area of Steam Piston

To arrive at the area of steam piston, where steam pump is used, there are also many complicated formulae, but for our purposes, another simplified arithmetical formula may be used which will very closely approximate good standard pump practice:

To obtain area of steam piston of a pump, when area of water piston is known:

$$S = \frac{(WL) + 100\%}{\frac{1}{2}P}$$

Where
W = Area of water piston.
L = Pressure per square inch on water piston. (i.e. that due to both suction and discharge resistance.)
P = Pressure per square inch on steam piston.
S = Area of steam piston.

Example
Area water piston, 78.5 sq. inches.
Combined suction and discharge pressure on water cylinder = 40 lb.
Pressure on steam cylinder = 35 lb.

Then
$785 \times 40 = 3{,}140.$
$3{,}140 \div 17.5 = 179$ square inches, or 15-inch diameter steam piston.

We see then that a vacuum pump maintaining approximately 10 inches of vacuum and discharging against boiler pressure of 35 lb., and serving 30,000 sq. ft. of radiation would be a pump 15 in. × 10 in. × 12 in. stroke × 50 strokes per minute.

Good Standard Practice

There is shown in Fig. 1 a complete layout of boiler and pump piping according to good standard practice for a two-pipe vacuum system, using a steam vacuum pump and returning directly from the vacuum pump to the boiler, without the use of an intermediate receiver and boiler feed pump.

The vacuum return line is shown returning in a trench, a lift pocket is placed when it rises to connect to the pump, a plugged tee being placed at the bottom; a grate valve is next in the line, followed by a suction strainer with removable cover, and a small plug in the bottom; connection to the suction opening of the pump is made full size of the pump tapping, and from this enlarged section a connection is taken to the automatic vacuum pump regulator and a small line extended to the vacuum gauge on the gauge-board.

The pump regulator automatically opens and closes the line from the boiler pressure, to operate the pump; this line is provided with a by-pass for use in case the regulator is out of service, and an automatic lubricator is connected into the side of the steam line to the pump. A small line is carried over and connected to the L. P. gauge on the board.

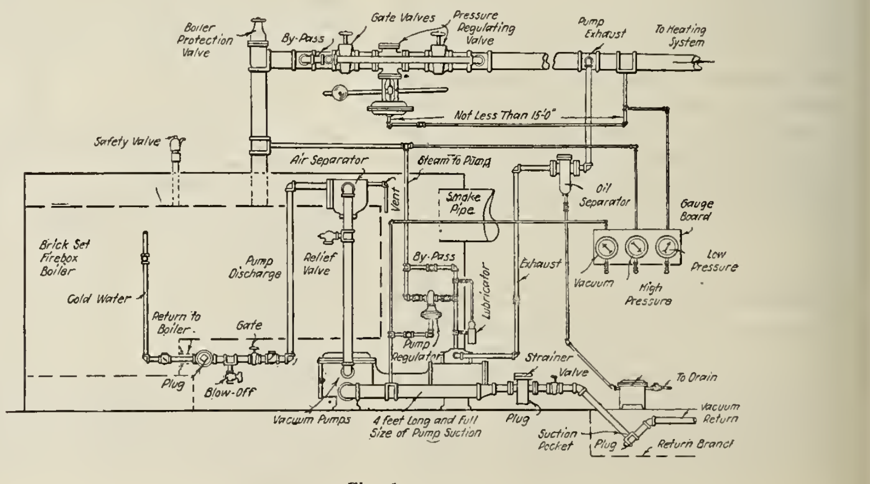

Fig. 1.

The line carrying the exhaust from the pump is connected back into the heating system on the low pressure side, an oil separator being placed to remove surplus oil and condensation before connection is made to the system; the oil separator is drained by an oil trap which discharges directly to the sewer or drain.

Suction of Pump

The suction of the pump carries all of the condensation from the heating system, as well as all the air. It must discharge the former to the boiler, and vent the air to the atmosphere. This is accomplished by carrying the discharge line from the pump vertically upward, and placing a vent trap, or air separator, on the top of the line; this device consists of a chamber containing a float mechanism which holds a valve port open to the atmosphere until the water within the chamber rises sufficiently to close it; in this manner the discharge to the boiler is entirely freed of air. In order to prevent accident to the air trap or collapse of the float, should the gate valve on the discharge line beyond the trap be closed, a relief valve is placed below the trap; the discharge to the boiler enters one side of a cross, cold water entering the opposite opening, and the return to the boiler being taken from one end of the cross, the opposite to that being plugged for cleaning purposes; a gate and check valve is placed on the pump discharge, and also on the cold water supply, and a blow-off as indicated from the bottom of the return header.

All of these connections are outside the brick-work.

Steam to supply the pump and the heating system is taken from the top of the boiler, a tee for the pump and gauge being placed immediately at the boiler. The riser extends to the topmost point, where a "boiler protection valve" is placed; the function of this is to assure sufficient pressure to operate the pump; if below that, no steam will be allowed to get into the heating system.

Beyond this valve the pressure regulating valve is placed, equipped in the usual manner with two gate valves for cutting it out of service, and a smaller valved line by-passed around all of these valves, for use when the pressure regulating valve is cut out. From a tee located 15 feet or more distant, a ¾-inch line is taken and carried to the bottom of the diaphragm which operates the regulating valve from the reduced pressure side; a ¼-inch line is carried from this same branch to the low-pressure gauge on the gauge board.

Clarence McNaughton Steeves, B.Sc., has been appointed construction engineer of the N.B. Hydro Commission, St. John N.B.

L. L. Craig, formerly manager of the hydro electric system at Stamford, Ont., has been appointed manager of the hydro electric system at Petrolia, Ont.

Show Value of Electric Power

Annual Meeting and Exposition of Association of Iron and Steel Electrical Engineers Held at Buffalo, N.Y.

THE annual meeting of the Association of Iron and Steel Electrical Engineers was held in the Broadway auditorium, Buffalo, Sept. 24 to 28. The program included 17 technical papers, meetings being held at 9.30 a.m. and 2.30 p.m., on Monday, Tuesday, Wednesday and Thursday.

In accordance with the policy inaugurated several years ago, an exhibit of electrical equipment for use in the metal-working industries was held in connection with the convention. About 120 manufacturers took space at the show, exhibiting a wide variety of motors, control equipment, and other accessories.

About 20 companies co-operated in the operation of a miniature foundry, the principal units of which were a small electric furnace, molding equipment, sand-mixing machinery, cleaning apparatus, and the necessary accessories.

Many foundrymen will recall that an attempt was made several years ago at a meeting of the American Foundrymen's Association, in Atlantic City, N. J., to produce hot metal in a miniature plant erected on the steel pier. It developed that the expense, inconvenience to other exhibitors, and obstacles arising from lack of proper facilities, prevented the plan from being executed successfully. This early attempt was made before the electric furnace had been developed to its present state of reliability and, therefore, the unforeseen difficulties in connection with the operation of an electric furnace plant under the restrictive conditions at Buffalo cannot be studied in the light of the experience of the Atlantic City trial.

The majority of the 1923 exhibitors displayed equipment used in the application of electricity for producing iron and steel, such as motors, control systems, panels, wiring details, insulators, recording meters, fuses, switches, transformers, and electrical heating equipment.

Another feature of the general exhibit was the display of accessories used in applying electrical power. This classification included such products as ball and roller bearings, valves, lubricants, bearings, gears, flexible couplers, pinions, etc.

Still another group of exhibitors offered equipment for the production of power from the combustion of fuel, such as boilers, refractories, arches, pumps, superheaters, turbines, etc.

The Association of Iron and Steel Electrical Engineers is in its sixteenth year, and during the past few years has grown rather rapidly, owing to its activity in encouraging the discussion of problems related to the application of electricity to the iron, steel, and metal working industries.

The technical program included a number of papers on subjects that have created a great deal of attention among electrical engineers in the steel industry. It is noteworthy that while eight separate sessions were provided, only 17 papers were scheduled. This arrangement gave ample time for the presentation of each technical paper and also afforded ample opportunity for the thorough discussion of each paper.

Operators and engineers interested in blast furnace problems were interested in the papers on skip hoist characteristics and traverse control of ore bridges presented Tuesday afternoon. Fuel problems were considered in papers presented at the Thursday morning session, while factors in the generation of steam were discussed in the afternoon.

The annual banquet was held at 7 p.m., in the ballroom of the new Hotel Statler, Thursday, Sept. 27. No technical session was scheduled for Friday afternoon, this time being left vacant for those desiring to attend the exposition.

The exposition was open from 9 a.m., to 6 p.m., every day of the convention, and remained open Wednesday from 7 to 10 p.m.

THE WORD "ENGINEER"

Mr. Editor, the word "Engineer" has the whole world in a quandary, for it's so incorrectly used and terribly abused that the word seems to need the laundry.

A "civil" calculates things right, usually works half the night, and his pay is too small to mention, while the "efficiency engineer" 'tis true, he "does things nights too," and his methods are a quite recent invention. He claims to doctor your "biz," owns a better car than a "Lizz," collects real money—or at least that's his intention.

Some engineers are known as operating or gas, and for almost any trade the title seems to pass. Some engineers rely on muscles, some on brains, while some use only steam to move stumps, rock, dirt and trains.

Now, Mr. Editor, I believe you and I agree that some day engineer will be correctly used and defined and less abused by those so inclined and the fellows who right it will include you and me, and 5,000 others who will compose the real engineering association.—C. A. S. E.

Carbonates of lime precipitate out of water heated to 212 deg. F. as in an open heater; but the sulphates require 250 to 270 deg. F. before they will precipitate by heat alone.

Eliminating "Grunts" in the Power House Pump

By **PUMP ENGINEER**

Clamp, Bronze Bushing and Litharge Stop Leakage on Brine Circulating Pump — Faulty Lubrication Causes Noise in Steam Pump—Change in Lubricator's Position Ends Trouble

A FEW weeks ago I was called upon to remedy some troubles in connection with two pumps in a Montreal plant. The first case I took in hand was a large duplex brine pump. One stuffing box was leaking badly, although the piston rod was in very good condition. By close examination I located the crack on both sides of the stud bolt hole, as shown in Figure 1.

On the outside the crack extended back about half the length of that part of the casting composing the stuffing box. In order to make a thorough examination and permanent repairs, I had the piston rod removed and found that the crack on the inside extended back to the bottom and partly across.

In order to stop the leak it was apparent that more than one expedient would have to be resorted to.

Repairing the Leak

First the clamp was made. Then a piece of 1-16 inch sheet packing was cut wide enough to cover crack on the outside. Next, some litharge putty was applied to the sheet packing and laid in place on the clamp. When the clamp bolts were drawn up tight this, of course, forced the litharge into the crack and filled any unevenness at this point.

In the meantime the bronze bushing, one-eighth of an inch in thickness, was an easy driving fit. Before driving the bushing into place, the outside was well coated with litharge in order to fill the crack on the inside of the stuffing box. Next the thread on the stud or gland bolt was cut the full length of the bolt in order to use a lock nut to cover the crack on the front of the casting. The side of the lock nut next to casting was well coated with litharge and screwed tightly into place.

The bronze bushing, of course, reduced the width of the packing space, which made it necessary to send for split packing rings of the proper dimensions.

While waiting for the new packing rings, the litharge had ample time to set.

In Use Twenty-four Hours

This pump is now in use twenty-four hours per day, seven days per week, and there is practically no sign of leakage. Before these repairs were made several pails of brine leaked out of the stuffing box each day.

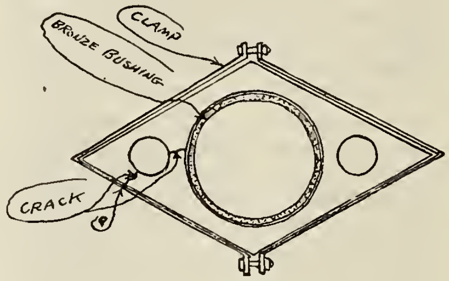

Fig. 1.

Next I looked over the other pump, which is an old type duplex tank pump, size 7½x7½x6. These pumps are often referred to as atmospheric pumps because they are built for pumping water under low heads or pressures but little above the atmosphere.

All considered, the pump handled the water better than would be expected taking into consideration its construction, and also that the water pressure required is about thirty pounds, but "she grunted badly all of the time" was the expression used by one of the men employed in the engine room, and the "grunt" was always in the steam end. Sometimes the noise was louder than at other times. When liberal qualtities of cylinder oil were used the pump would run reasonably quiet. About a gallon of cylinder oil had to be used per twenty-four hours. This was rather expensive, considering that another pump of about four times the capacity required only about one quarter as much.

Noise on One Side

When listening with the ear close to the steam chest cover, the noise appeared to be on one side only and it sounded as if there was a dry spot between the valve and its seat. When the valves were examined they were found in good condition. There was plenty of side clearance and in so far as the writer could see there was nothing to prevent the oil from reaching all parts.

However, when looking over the steam connection I saw that the pipe was led some little distance in a horizontal position to the steam chest. The double connection lubrication was connected to the riser to the main steam line as in the usual way, and although the horizontal connection was longer than usual there was nothing to show that this was the cause of the trouble. Several different kinds of cylinder oil were tried, but as the pump still continued to indicate audibly that none of these oils had reached the dry spot, the writer removed the steam chest cover and had a hole drilled and tapped for one inch pipe thread, and connected the column for the lubricator, as shown in Figure 2. The idea is to have the oil enter the steam chest directly over the valves.

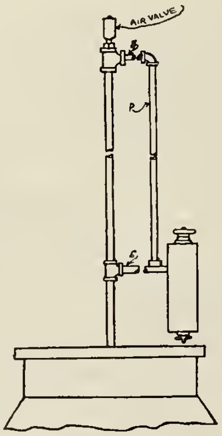

Fig. 2.

The Trouble Located

This arrangement did not seem to improve matters any, at the start, because where the pump was started again the "grunt" was as loud as before, and after about an hour the lubricator stopped feeding. The trouble was located in the upper part of the column, which had become air bound.

The confined air prevented the steam from entering pipe P where it is condensed, and since this type of lubricator depends on the column of water, or pressure due to the head of water to force the oil out through the feed nozzle, the lubricator was useless under these conditions, but when the air valve was located as shown, this released the air. The "grunt," however, "was still on the job." Strange as it may seem, after about twenty-four hours the noise gradually died away, and the pump is now running as quiet as any of the other pumps in the plant.

During the cooler months this pump is operated continuously twenty-four hours per day. It now requires only one and one-half pints of cylinder oil, and compared with the amount previously used the saving is considerable.

Remarks on the principle of hydrostatic or double connection lubricators may seem out of place under this title, but from remarks I heard by men employed in this plant, and by men employed in other plants, it seems that some men are not fully acquainted with the principle of this type of lubricator.

They have the idea that the lubricator depends on steam pressure for its operation, or that the steam pressure forces the oil into the steam chest. In a measure this is so, but mainly the lubricator depends for its operation on the displacement of the oil by a body of water which is formed by the condensing of steam in the pipe P, Figure 2. The condensed water passing into the body or oil chamber displaces the oil, forcing it up through the feed nozzle. The oil then rises to the surface of the water in the sight feed glass

Boiler Feed Water Evaporation and De-Aeration

Operating Engineers Devoting Much Energy To-day to Purification of Make-up Feed Water and Prevention of Corrosion in Plants Throughout the World

TWO important questions receiving the attention of operating engineers throughout the world at the present time are the purification of the make-up feed water and the prevention of corrosion in the boiler plant. In the scientific treatment of the water supplied to the boilers lies the solution to the serious troubles and expense arising out of the corrosion of economizers and boilers; and the elimination of the causes of corrosion will widely extend the range of utility of ferrous metals for turbine blading, and thus enable turbine builders to meet the exacting requirements of modern conditions with less difficulty.

The problem resolves itself into two parts: first, the provision of make-up water free from solids and scale-forming matter; second, the elimination of all corrosive gases in the water discharged to the boilers.

Many plants to-day use a softening apparatus to eliminate the calcareous and magnesium salts which are usually present in raw water, but this process, while lessening the formation of hard scale, does not appreciably modify the total weight of solids in the water. Often the result is that the solids become concentrated in the boiler and, unless the boilers are frequently blown down with the consequent loss of heat, priming takes place with its attendant evils.

Cut Blow-Down Losses

One of the duties of the engineer is to reduce blow-down losses to a minimum by keeping the concentration as high as possible, and at the same time to avoid priming. This concentration of solids in the boilers becomes a serious question under peak load conditions, because it places a very definite limit to the steam generating capacity of the plant. The use of pure feed water avoids the blow-down loss and also permits the boilers to be operated at a very much increased rate of evaporation to meet peak conditions without danger of priming. It thus increases the efficiency of a boiler plant and enables a smaller plant to meet a given steaming output.

For these reasons the use of distilled water from evaporators is rapidly finding favor with power plant engineers. In many cases a very inferior water is obtainable without expense, and by means of an evaporating plant, this water can be converted into pure distilled water when otherwise the make-up would be taken from the town supply, at considerable expense; moreover, even town water often requires treatment before it can be fed into the boilers.

In Multiple Effect

Evaporation can be carried out in single or multiple effect, and assuming the make-up to be evaporated is five per cent. of the station feed, the steam required is six per cent., 3.5 per cent. and 2.2 per cent. for single, double and triple effect working respectively. Of the heat supplied to the evaporator at least ninety-five per cent. can be absorbed in the main feed water; thus with single, double and triple effect systems, the feed water can be raised 60, 35 and 22 Fahr. respectively at full load, and the system to adopt should be that which allows the recovery of this heat under all working conditions.

The size of evaporator required for a given output depends chiefly upon the temperature difference between the steam supply and the vapor leaving the evaporator, and, for a given temperature difference, the capital cost of the plant will increase in proportion to the number of effects used.

This is easily understood if a single effect evaporator and a double effect plant working under the same conditions be compared. In a double effect plant for a total output of three tons per hour (that is, one and a half tons from each effect, each working on half the total temperature difference), each evaporator would be the same size as a single effect evaporator giving three tons per hour and using the total available temperature difference.

Fig. 1 shows a horizontal evaporator of the "Contraflo" type and it may interest Canadian engineers to know that the Goldie & McCulloch Co., Ltd., of Galt, Ont., are the Canadian licensees for the manufacture of this evaporator, as well as "Contraflo" high vacuum type condensers and feed water de-aerating apparatus. In the evaporator illustrated the coils are secured in groups of four to parallel headers. The couplings are of simple and rugged design, the inlet and outlet ends of each group being secured by a single bolt.

The formation of the coils is such that when steam is admitted to them, any scale which may have formed outside is cracked, falls to the bottom of the evaporator, and is then discharged through the evaporator blow-down.

For a moderate steam pressure, the well-known vertical type, as shown in Fig. 1, is preferable; this type is a development of the marine evaporator and embodies experience gained over a considerable number of years.

The evaporator illustrated in Fig. 3 is a special design for low-pressure working, and consists of two parts, a heater and a flash chamber; the make-up water to be evaporated is circulated through the heater tubes, which are surrounded by low-pressuer steam, and the water, after being heated, is sprayed into the vacuum in the flash chamber.

The heat absorbed by the water in passing through the heater is given off in the flash chamber in the vapour released by the fall in temperature, and the water falling to the bottom of the chamber is again cir-

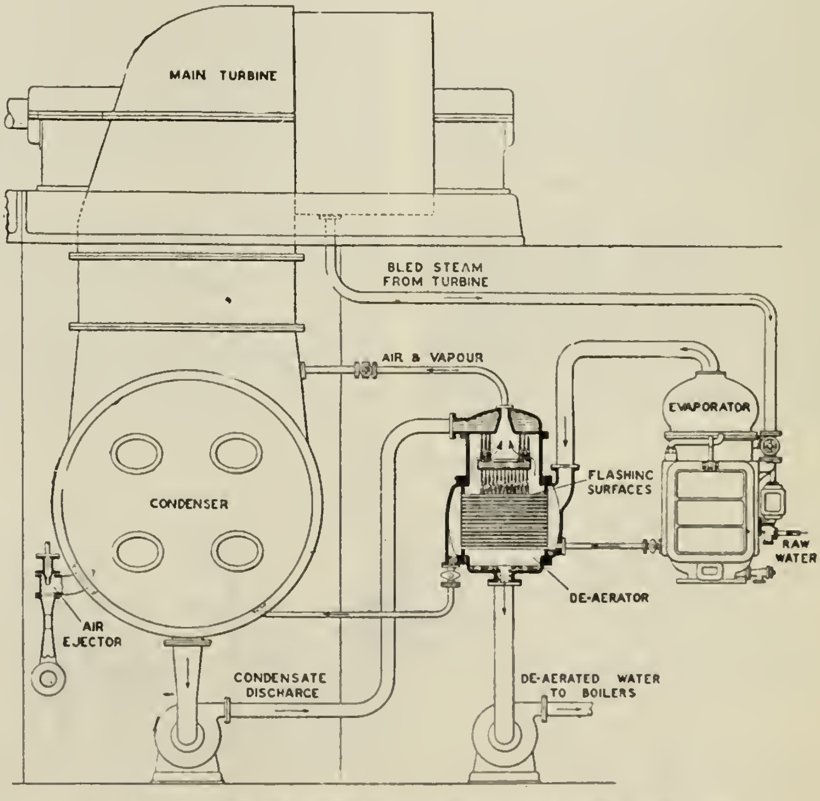

Fig. 1—Vertical evaporation and de-aerator for a single power unit.

culated through the heater. This evaporator possesses two important advantages: the scale-forming solids are kept in solution during the passage of the water through the heater (and thus the formation of scale on the heating surface is avoided), and as the circulating pump is arranged to discharge against a pressure greater than atmospheric, continuous brining is a simple operation, even though the evaporator is operating under a vacuum.

Turning now to the question of the elimination of corrosive gases, chemical research has definitely established that the corrosion of iron and steel in the presence of water is almost invariably due to the action of oxygen which is present in solution in the water. Water exposed to the atmosphere absorbs oxygen with great avidity, and the lower the temperature of the water, the greater the quantity of oxygen it will take up in solution.

Fig. 4 shows the approximate oxygen contents of water at various temperatures when exposed to the atmosphere.

As an example of the oxygen contents of feed water in an open feed system of a typical power plant, it is interesting to note that the water discharged by the condensate pump was found to contain 0.9 cubic centimetres of oxygen per litre. By the time the water was halfway through the system it had absorbed so much air from the atmosphere that it contained 3.55 c.c. per litre, and when measured at the discharge of the feed pump to the boilers the oxygen contents were 3.75 c.c. per litre. The make-up in this plant is taken from the town supply and contains 7.5.c.c. per litre.

Because of these facts modern power plants are being fitted with the closed feed system in which the condensate drawn from the condenser is returned to the boilers without being exposed to the atmosphere and thus the absorption of oxygen is prevented.

The closed feed system, in itself, is not sufficient to secure immunity from corrosion, since the condensate extracted from the condenser contains oxygen in solution. The quantity of oxygen it contains depends upon the vacuum in the condenser, the temperature of the condensate, and the air pressure at the condensate pump suction.

As an average figure the oxygen contained in condensate, when discharged separately from a condenser, may be taken as 0.5 c.c. per litre, but it is possible to reduce this figure if the plant be fitted with an efficient air pump, and the air leakage kept to a minimum, by maintaining the vacuum system as air-tight as possible, a condition which demands constant care and attention.

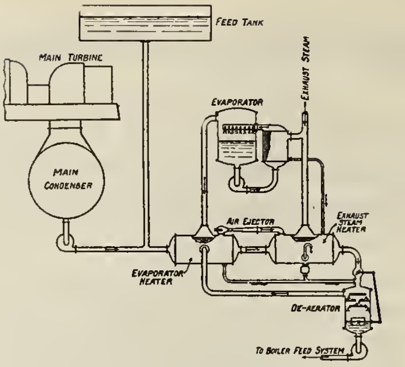

Fig. 3—Special combination using exhaust steam.

Engineers to-day are demanding that the feed water delivered to their boilers should be de-aerated to the extent of at least 0.1 c.c. per litre. Where steel tube economizers are used, a greater degree of de-aeration is desirable, and with well-designed de-aeration plants it has been found that every measurable trace of oxygen can be removed.

Water sprayed into steam gives up a certain proportion of the contained air in being heated, but this process alone is not enough for efficient de-aeration. In a power station in which the condensate and make-up are discharged together into a direct contact heater, the water was found to contain 5 c.c. of oxygen per litre before passing into the heater, and, although the oxygen contents were reduced, the water leaving the heater still contained 1.1 c.c. per litre.

Tests have proved that complete de-aeration can be obtained by supplementing direct contact heating by flashing the heated water on a surface of high temperature under a vacuum, so that the water is shattered into minute particles and the complete liberation of the contained gases thereby effected. This flashing process is the principal feature in the design of the de-aerator shown in Figs. 1 and 2. This de-aerator is self-contained, and possesses a bank of steam-heated tubes over which the water is sprayed.

The vapor rising from this hot tubular surface heats the falling water to boiling point in the upper part of the de-aerator by direct contact, and partial de-aeration is effected. The partly de-aerated water then comes into contact with the hot tubes and is completely disintegrated as it falls from tube to tube, the remaining air being liberated and withdrawn at the top, while the air-free water flows out at the bottom on its way to the boilers.

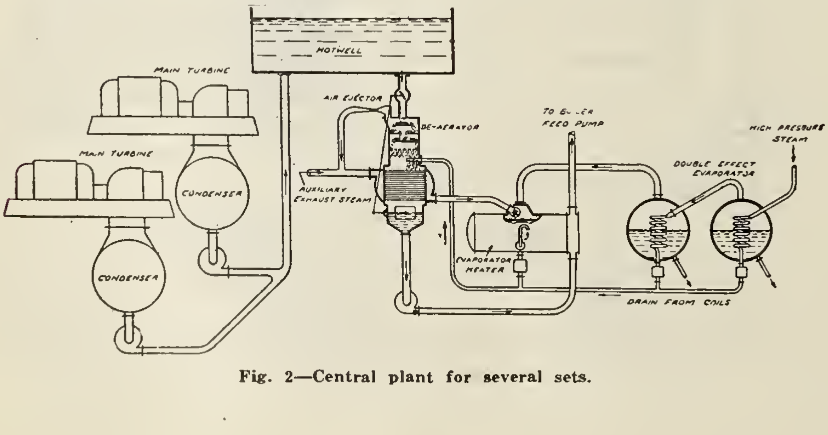

Fig. 2—Central plant for several sets.

The action of this de-aerator is such that, not only oxygen, but all other gases are eliminated to the same extent in relation to their solubility. The necessary vacuum in the de-aerator is maintained by a small steam-operated ejector, or by a connection to the main condenser, whichever is the more convenient.

This de-aerator, being also a heater, can be fitted so that a separate heater is not required, and it is particularly suited for operation in place of the usual bleeder heater. Where auxiliary steam containing oil is available, it makes use of the steam without allowing the oil to mix with the de-aerated feed water. It can be fitted very easily into existing plants, does not require the careful attention necessary with chemical de-aerators, and its efficiency is not affected by variations in the feed water supply.

Evaporators and de-aerators are complementary in their functions in a power plant, and can be arranged to operate together as shown in Figs. 1, 2 and 3. Fig. 1 shows an economical system for use in connection with a single power unit. The make-up water is fed into the evaporator and the steam required for its evaporation is bled from a low-pressure stage of the turbine.

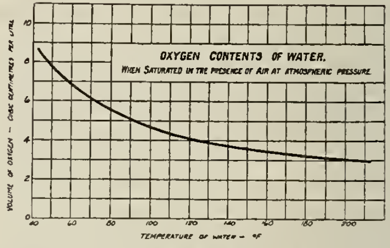

Fig. 4—Curve showing normal oxygen contents.

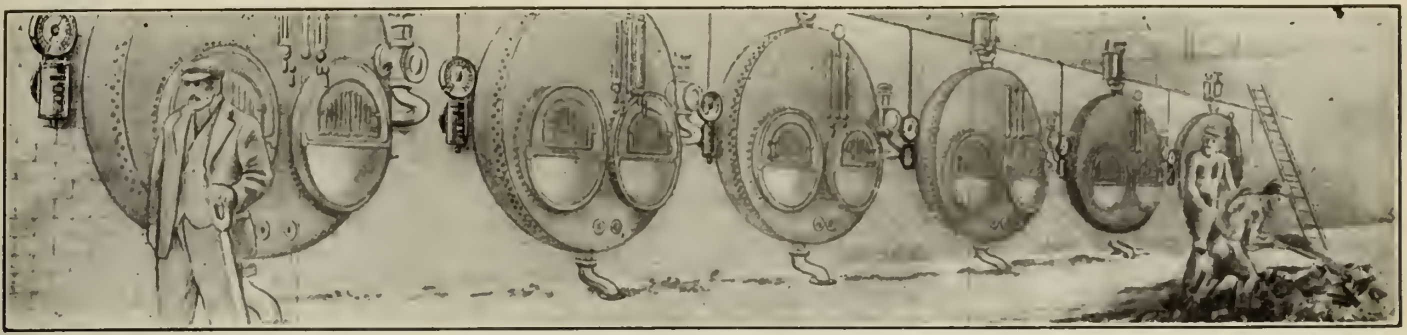
The vapor generated in the evaporator passes into the heating surface of the de-aerator, where it is used to heat and de-aerate the condensate passing through the de-aerator on its way to the boilers. The drains, after passing through the main condenser, are de-aerated along with the main condensate.

The arrangement in Fig. 2 shows a high-pressure evaporating plant of two effects, providing distilled make-up water for a number of power units. The condensate from all the power units is discharged into an elevated hot well or storage tank, from which it flows into the de-aerator. A float, placed in the base of the de-aerator, controls the inlet of water in accordance with the requirements of the boiler feed pump. Auxiliary exhaust steam is used in the heating surface of the de-aerator and the surplus passes into the evaporator heater which receives the vapor from the last effect. The de-aerated feed water in passing through this heater is heated to a still higher temperature.

The various drains are collected and passed into the de-aerator where their heat is conserved and they are de-aerated along with the main condensate.

A small steam-operated ejector maintains the vacuum in the de-aerator, and discharges along with the heating steam in-

(Continued on page 44)



Easy Engineering Lessons in the Power House

By M. BARRY WATSON, B.A.Sc., M.E.
Director of Engineering, Central Technical School, Toronto.

IN REVIEWING for the American Society of Mechanical Engineers, a well-known engineering handbook, which has been entirely rewritten and put on the market during the last few months, a critic writes in part as follows: "......at last the hand fire has been relegated to the place it belongs—obscurity."

The writer of these lessons cannot agree with the above mentioned critic, because he feels that there are still many instances where hand firing can not profitably be replaced with automatic stokers. The engineer, who made the above criticism, is no doubt accustomed to dealing with the power and heat problems of the larger central stations, and appears to consider the small one-man plant and the seasonally operated plant as negligible.

In the light of the total amount of fuel burned and the national economy of operation of such small plants, they may be negligible. They are nevertheless of just as great importance to the owner, as the largest plants are to their owners, and therefore, any economies which can be effected in the small plants are relatively just as important as in any other plant.

Results in Savings

Where temporary or intermittent service is required from a plant, or in small heating plants which are operated during only a portion of the year, it would probably be found that the interest and maintenance costs on a stoker installation would more than offset the slight saving in labor and fuel which might be effected over hand fired equipment. Thus hand firing is still an economic proposition in some plants.

There are in Canada many such plants. Also under the present conditions of commerce and finance, few plant owners are willing to increase their capital investment except where it will mean a decided increase in production. Even though such owners are assured that such changes as the installation of automatic stoker equipment will result in sufficient saving in operation to more than meet overhead charges produced thereby, the capital required for such alterations is hard to get, and even if available could probably be used more effectively if invested in other parts of the business.

For the above reasons hand firing is bound to be carried on extensively for many years yet, and it would be a serious mistake for engineering publications to ignore this topic. In any case the same principles apply in the combustion of fuel under hand fired as under stoker fired conditions, especially when the latter conditions are associated with natural draft.

Fuel on the Grates

Coal never burns at a uniform rate over the whole fuel bed. This may be for any of numerous reasons, such as, one shovel of coal may contain more slack, while another shovelful may contain a large proportion of lumps, in which case the resistance to the flow of air through the finer coal will be great enough to prevent it burning as fast as the lumpy coal; or the air flow may be partially obstructed in some areas by accumulations of clinkers or hard crusts of coal, and the coal will naturally burn fastest where the air flows most freely. Because of this uneven burning, thick and thin spots are sure to develop in the fire. Wherever the fuel burns most rapidly, the thin spots are sure to form.

The fresh coal should always be placed on the thin spots of the fuel bed. Before throwing the coal into the furnace the fireman should take a quick look to locate these spots. Since the thin spots are those in which the fuel has been burning fastest, they will easily be recognized as being the brightest spots in the fire. The thick spots will either be very dull or will be burning with a sluggish smoky flame.

In endeavoring to level up the fire in this way it will be found much easier to place the coal where required if small rather than large shovelfuls are taken. The thinnest spots in the fire should not be filled up level at one firing, especially if a coking coal is being fired, or this coal may fuse into a solid crust, which will effectively choke the flow of air at any point, causing slow combustion and starting a new thick spot.

Cause of High Spots

Since high spots are caused by coal not burning fast enough at these points, the fireman should not place more fuel on them, or he still further checks the draft, thus aggravating the condition. If the slow combustion in the high spots is caused by dirty or slack coal or by a hard crust on the surface of the fuel, this will gradually burn through or crack, as long as it is not covered with fresh fuel, thus allowing a free flow of air and the spot will come back to normal.

Of course, if the high spots are caused by clinkers obstructing the flow of air from the grates, the fire bed can not become normal until after the clinkers have been removed.

If the thick and thin spots become so troublesome that the load can not be carried while the fire bed is being levelled up in the above manner, it may be necessary to break up lumps of caked fuel and spread it evenly over the grate with the rake. This levelling process is just so much extra work for the fireman, which in most cases could have been avoided by the proper placing of the fuel. It is also wasteful of heat, as it allows an excess of cold air to pass through the furnace.

In levelling care should be taken not to disturb the ashes, or clinkers will be almost sure to form, which will aggravate the slow combustion in spots. Large lumps of coal are another fruitful source of uneven fires. No lumps bigger than the first should be placed in the fire.

A skilful fireman is able to keep his fuel bed level for hours by placing the coal properly. The unskiled man often has to rake his fires every second or third firing, thus handling a large proportion of the coal twice. He will also have much more work in cleaning the fires, which is really the hardest and most disagreeable part of the work in the boiler room.

Thickness of Fires

A good general rule for hand-fired furnaces burning run-of-mine coal with natural draft is to keep the thickness of the fire between four and eight inches. If forced or induced draft is used these figures may often be considerably exceeded. When the coal consists mostly of lumps and large pieces the thickness may be greater than when the coal contains much slack or fine pieces.

Since the capacity of a boiler is almost directly proportional to the amount of fuel which can be completely burned on the grate, it will be found advantageous to keep the fuel bed in such state that it will burn at the fastest possible rate if required. In order that the fire may burn fast, large quantities of air must pass through it. Thus the resistance to the flow of air through the fuel must be low, which means a comparatively thin fuel bed.

Cuts Boiler Capacity

Every pound of coal requires from fifteen to twenty-five pounds of air for its complete combustion; therefore, with a thick fire allowing only a limited amount of air to pass through, we will either burn a small quantity of coal, thus cutting the capacity of the boiler, or we will incompletely burn a very large quantity of coal and lose three quarters of its heat value in unburned gases going up the chimney. A thick fire is also one of the most prolific sources of clinkers.

Some engineers may not agree with the above statement because they have been brought up to believe that too much oxygen is liable to pass through a thin fire without uniting with the carbon. This is, however, a mistaken idea for tests have shown that the gas coming off from even fuel beds three or four inches thick, contains less than two per cent. of free oxygen, while there may be in it up to twenty-five per cent. of unburned gas which requires still more air to be admitted above the grates before combustion will be complete. With a thicker fire there is likely to be considerable smoke and soot given off, especially when a fresh charge of fuel is put on.

It would thus appear that a few small holes in the fire would not be a serious fault, as the air which would come through them would serve to complete the combustion of the unburned gas rising from the fuel bed. If, however, the holes were big, the air would not be likely to mix intimately enough with the gases to burn them, and would therefore serve only to cool down the boiler.

Of course it takes more skill to handle a thin fire, but a good fireman is proud of his skill, for when it is properly used in firing it saves fuel for the employer as well as saving work for the fireman in reducing the coal, ashes and clinker to be handled.

(To be concluded in next issue)

The town council of Jonquierre, Que. are contemplating a $75,000 addition to their hydro-electric plant.

C. A. S. E. Notes

A special meeting of Toronto No. 1, C. A. S. E., was held on Monday, Sept. 24, at Cumberland Hall to introduce R. S. Rutherford, Director of Technical Education for Ontario, to the members. Mr. Rutherford, honorary chairman of the education committee of the C. A. S. E., in an address urged engineers to attend the classes in stationary engineering in the technical schools throughout the province. He described the new booklet, recently issued by the Department of Education, which covers the requirements of each grade of certificate.

The department will initiate classes in any part of the province if a sufficient number of applications are received.

T. H. Fenner, in outlining the work of the educational committee of the C. A. S. E., said that engineers ought not merely to aim at securing the minimum of knowledge required to obtain the necessary certificates, but should endeavor to qualify themselves for better positions.

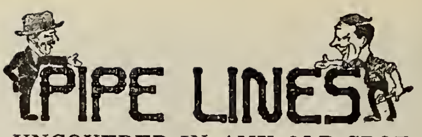
The policy of the educational committee this year is to make the meetings practical as well as theoretical, the question box will be retained and the relation of costs to the production of power will be briefly dealt with when the opportunity is presented.

A series of half-hour lectures will be prepared by different members of the committee dealing with combustion, steam heating, refrigeration and electricity. These lectures will be typed and sent out to the different lodges, so that the absence of someone capable of delivering a lecture will not interfere with the educational program.

G. M. Brown, chairman of the Ontario Board of Stationary and Hoisting Engineers, attended the meeting and replied to numerous questions in regard to the certificates issued by his department. In the discussion which followed, an interesting fact in regard to some of the laws of the province was brought out. It is perfectly legal to leave a heating boiler under steam all night without any attention, but if a night watchman is employed, he must have a certificate.

The meeting, which was open to the public, was well attended, but the visitors, with one exception, seemed loath to take part in the discussions.

A board for the examination and regulation of the licensing of electrical contractors and workers has been appointed in Toronto, the members being: Henry Rohler, representing the electrical contractors; George Summer, Sr., representing the electrical workers; Percy T. Gaston, representing the electrical inspection department of the Ontario Hydro Commission; and W. G. F. Price, city architect. After October 1, electrical contractors and workers must be licensed.



PIPE LINES

UNCOVERED IN ANY OLD SPOT

There was once a maiden of Siam,
Who said to a fireman, young Kiam,
"If you kiss me, of course
You'll have to use force,
But I'll wager you're stronger than I am."

* * *

It is not necessary that the copper bars in the rotor winding of a squirrel-cage type induction motor be insulated from the core for satisfactory operation. In fact, many of the modern induction motors are built without any insulation whatever.

* * *

A peanut sat on the C.N.R. track,
Its heart was all a-flutter;
The 3.45 *came thundering past—*
Toot! Toot! Peanut butter!

* * *

Before starting a commutating-pole type rotary converter, the brushes should be raised before starting and lowered after the machine is synchronized at full voltage; otherwise severe sparking will occur at the brushes.

* * *

A Halifax engineer wrote in the other day asking if a burglar entered a fuel yard would the coal chute? Our new blonde reporter who happened to see the query said that she didn't think so but she was certain the kindling wood.

* * *

An alternating current differs from a direct current in that the latter flows only in one direction in the circuit, its value at any instance being determined by the resistance on the circuit, whereas the alternating current is continually changing its direction.

* * *

An able engineer now has come along to tell us about getting electricity out of coal, which no doubt, accounts for the shock we experience when we receive our bill.

* * *

The comparative capacity of synchronous converters on a basis of average heating at unity power factors to that of a direct-current generator, where the direct-current generator capacity is taken as equal to 100; the same machine operated as a single-phase converter; will be 85; operated as a three-phase converter 134; as a quarter-phase converter 164; as a six-phase converter 196; and as a twelve-phase converter 224.

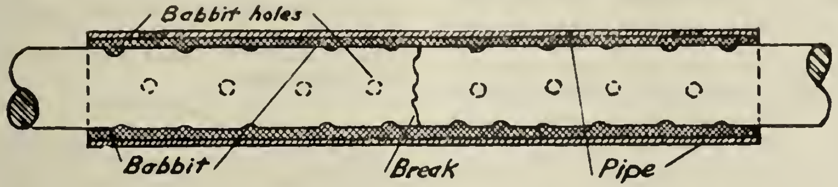
Writing from Winnipeg, Walter Hudson says: "I refuse to take a drink unless it is given to me in a tin cup, so that I can have the cup to beg with in case I go blind."

Practical Ideas From Practical Men

REPAIRING BROKEN SHAFT

In the power plant of a paper mill which I had charge of the 2-inch shaft driving the forced draft fans snapped in two; as a result the plant was completely shut down at a time when steam was most needed.

The plant was located far from civilization or any machine shop, and as a new shaft could not be obtained for some time, a temporary repair was made as shown in the sketch, enabling the plant to start up in two hours.



Small holes were drilled in the shaft with a breast drill for approximately 8 in. on each side of the break to give the babbitt a grip. A piece of 2½-in. pipe was secured and two ½-in. holes bored in line at each end, serving as pour holes.

One end of the shaft was pushed back to allow the pipe to be slipped on, then the broken shaft ends pushed tightly together.

The space between the shaft and the ends of the pipe was then stopped with clay, the pipe heated with a blow torch while hot babbitt was poured in to fill the ¼-in. space between the shaft and the pipe.

The babbitt, as it solidified and cooled, gripped the shaft tightly, the cooling of the outer pipe causing it to shrink tightly to the babbitt and make the job more secure.

The repair was intended only as a temporary measure and furthermore was done in a rush, but when the new shaft arrived some weeks later the babbitt job looked as if it would have lasted indefinitely.

—JOHN F. McKENZIE, Toronto.

PIPE BENDING HINTS

In bending large pipe, fill with dry sand and plug the ends. Heat to a red heat in localities to be bent and bend. Be sure that the sand is dry. Where bends are slight, it is often unnecessary to use sand or resin. The object of sand or resin is simply to keep the sides of the pipe from collapsing, or to prevent reduction of flow area. If wet sand is used, and if the ends are plugged, the pipe may burst when heated, due to the steam pressure generated.

Resin, also, is good. There is, however, a "right way" and possibly several wrong ways to use it. An example of a wrong way was recently brought to my attention where the mechanic filled the pipe with sand. The result was—a violent explosion.

The way to use resin is to pour it into the pipe and allow it to cool and harden. As soon as the resin is hard, bend the pipe cold. Don't heat it. Then after the pipe is bent, heat the pipe all over sufficiently to melt and remove the resin.

There are many excellent mechanical devices on the market for bending pipe. To bend large, stiff pipe slightly, and inexpensively, there is nothing handier or more efficient, in my judgement, than hydraulic pipe bender driven by a hand pump.—N. G. NEAR.

LUBRICATION OPERATION

The location of a hydrostatic lubricator with respect to the unit it is to lubricate should be at a convenient height above but close to the throttle valve. The independently acting type of lubricator is attached to the steam line at two points, one above the apparatus itself and one at the point, of discharge.

The length of the pipe connecting the upper attachment to the condenser bulb should be at least eighteen inches, in order to insure sufficient water pressure acting upon the oil within the lubricator reservoir to cause constant and regular flow of the oil through the discharge pipe.

When filling a lubricator, first close the valve in the oil discharge pipe and the value just below the condenser bulb. Then remove the filling plug and drain the lubricator by the bottom drain valve, before putting in new oil.

Adjust Flow of Oil

To put the lubricator in operation, open the valve in the oil discharge pipe, and also the water valve and then adjust the flow of oil by means of the regulating valve below the sight-feed glass. The regulating valve should not be opened for at least five minutes after steam has been turned on. This will allow sufficient steam to condense in the lubricator to fill completely the reservoir space not occupied by the oil.

If this precaution is not taken, steam will enter the lubricator and "churning" will occur. This churning will deposit globules of oil on the sight-feed glass.

If the oil drops appear to form too large, they may be reduced by filling the sight-feed glass with a solution of water to which about a teaspoonful of common table salt has been added. Increasing the specific gravity of the solution in the glass causes the oil drop to leave the feed cone before it has time to become too large. The formation of large oil drops is usually due to dirt collected around the top of the oil feed cone.

The sight-feed glass can be cleaned of dirt or oil deposits either by blowing steam through it or by swabbing with a piece of cloth. In the latter case remove the plug at the top, wrap a piece of lintless cloth around a thin stick, soak in kerosene, and swab the sides of the glass. Be careful not to allow any shreds to remain in the glass.

Open Drain Cock

When it is desired to clean by blowing through with steam close the oil-regulating valve below the sight-feed glass and then open the sight-feed glass drain cock in the bottom setting. Then by opening the valve in oil-discharge pipe, steam can be blown through the sight-feed glass to clean it.

In general leaky connections will cause irregular feeding of the oil. Should the sight-feed glass become clogged, it may be due to setting up too tightly on the bottom nut when the glass was installed. This often causes the rubber gasket to be squeezed out of place and perhaps into the glass. If the oil-feed cone should become displaced or off center, it may cause the globules of oil to move up the sides of the glass, and perhaps to stick there, causing the glass to fill with oil.

The glass should then be removed and the cone filed down, or it will be found effective to solder a fine copper wire to the side of the cone, leading it upward through the center of the glass, nearly to the top. The oil drop will then follow the wire, and the glass will remain clean. It is not advisable to allow a hydrostatic lubricator to run empty of oil, owing to the danger of the sight-feed and gauge glasses becoming hot, thus causing oil to stick and gum to the sides of the glass.

When a lubricator is installed where it is exposed to the weather, and there is danger of freezing, it should be shut off and thoroughly drained when not in use. When this is necessary an extra valve should be installed in the upper piping, close to the main steam pipe. All valves should be closed tightly in order to prevent leakage of steam and resultant condensation in the lubricator.

When a small, slow feed is required, it is often found difficult to maintain this uniformly owing to the changes in the viscosity of the oil by virtue of changes in temperature. Therefore, weather or engine-room temperatures may be factors that will necessitate more attention being given to the operation of the lubricator.—E. R. NEWTON.

EQUALIZER SHORT CIRCUITS

On multipolar, multiple-connected armatures trouble may be experienced, due to unequal distribution of the current through the several armature paths. This will underload some brushes and overload others, and if the current inequalities are too great, the overloaded brushes will spark.

The unequalized conditions are minimized as far as possible by cross-connecting some of the commutator bars which are at the same potential when the armature is in operation. In the diagram one equalizer is shown in dotted lines to connect three equipotential bars, another equalizer would connect three more and so on until the desired number are connected.

In a certain instance a six-pole armature came into the shop for repairs. Apparently, the trouble was a burnout among several leads where they were connected to the commutator. The leads were spliced, reinsulated and reconnected to the commutator. It was necessary to send the armature out without any conclusive test, because the motor frame was not available, and when subjected to a bar-to-bar test, an equalized armature will give indications similar to those obtained from an armature having short-circuited coils.

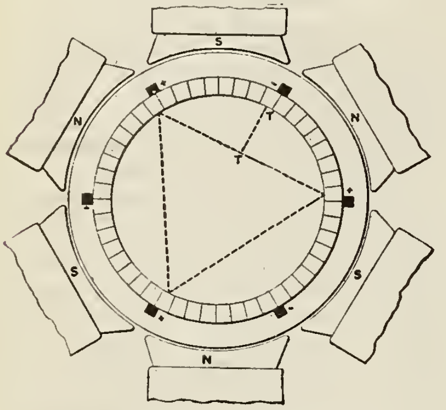


Diagram of short circuit on equalizer.

The armature was returned very soon with the complaint that it would "turn a little and then stop."

In the diagram the length of the equalizer is shown to connect bars located at points twice the distance between brushes. In this particular machine six sets of bars were equalized and the equalizing conductors were made up into a wreath and installed behind the commutator under the regular leads. As their overlying insulation had appeared to be good, the repairman had not disturbed it. Investigation disclosed that under the insulation two equalizer conductors had become short-circuited to each other in a manner such as to produce the condition indicated by dotted line *TT* in the diagram. Here it will be noted that the equalizer short-circuits the brushes. On removing the short-circuit, operation became normal, and no further complaint was made.—HYDRO ENGINEER.

LOCATING OIL TROUBLES

MOST operating engineers in these days make a very strenuous effort to conserve all the heat that is represented by the returns and condensate from heating coils, drying systems, etc., with the result that very often oil is encountered in the boilers, causing a scaly coating, or resulting in the bagging or blistering of tubes or sheets.

The presence of oil in the boiler is rather a serious matter and no operating man should tolerate such a condition, though in some cases the running down of the cause of the trouble will often seem to be baffling and difficult. Where trouble from oil in the boilers is experienced and the cause is not easily detected, it is advisable to approach the problem in a systematic manner, arriving at the solution by a process of elimination.

The factors that should have consideration are: (a) investigation of the character of the returns coming back to the hot well or heater to make sure that they contain no oil either in the free state or as an emulsion; (b) feed water heater should be examined to determine whether oil is being introduced with the exhaust steam at that point; (c) quantity and quality of oil used should be investigated; (d) an examination should be made of the raw water supply.

Frequent Cause of Trouble

Perhaps the most frequent cause of oil trouble is the admission of oil into the feed heater or hot well by means of returns of condensate. This happens because often exhaust steam is passed into the heating or drying system without first taking steps to remove the lubricating oil contained in the steam, and hence the resulting condensate carries with it all the lubricating oil impurity. Hence in all cases where exhaust steam is used in the heating or drying system, the purity of returns which are to be utilized for boiler feed should be insured by arranging to separate the oil from the steam by means of an oil separator on the inlet line. If the returns come from different sources a separator should furnish protection on each supply main. Care should be taken to see that the oil extractors are of proper size, are large enough to handle the steam passing through them, and that they are continuously and effectively drained.

Often it is found that while the main exhaust lines are protected with extractors, at some point or other in the system there is discharged some pump or small engine exhaust line not similarly protected, and because of the large amount of oil consumed by such small units, sufficient oil can be carried into the system to give trouble in the boilers. Hence this possibility for trouble should always be investigated.

Rource of Supply

Therefore, the first step is to investigate every single source of steam supply, and see that it is properly protected from oil entrance, or, another way, to see that proper oil filters or extractors are provided where the returns come off the system.

In one case the writer found the pump exhausting directly into the hot well tank in order to secure the heating effect of this steam, but no provision had been made to remove the oil other than occasional skimming off of the tank, and this did not remove all the oil that was present in emulsified form.

In order to detect the presence of oil coming back with the returns, these lines should be arranged so that samples of the condensate can be drawn and tested at intervals. The oil will show up in the water as a yellowish emulsion, or may even float on the surface of the water in free form.

Trouble in Heater

The next most frequent cause of oil trouble lies in the heater where the feed water is brought in actual contact with the exhaust steam. Normally these heaters are furnished with oil separators for first removing the oil from the steam, but it is well to check up this part of the equipment to see that it is all in working order, that the drainage of the apparatus is functioning, and that the outfit is not overloaded. Often putting too much steam through the heater will result in overloading and ineffective oil protection.

Interior inspection of this heating apparatus will often disclose whether the oil is coming in with the steam, or, if coming in with the returns, depending on where the coating of oil is found, and often the information so obtained will direct the engineer to the proper place to look for the trouble

Investigate to see whether any steam is entering the heater other than through the separator. Often an engineer will enter a small pump exhaust in the back of the unit without proper oil protection.

Another case was developed in which the operating man was feeding slight quantities of oil into his feed on the advice of some friend of his that it would help to cut down his scale troubles.

Poor Quality Oil

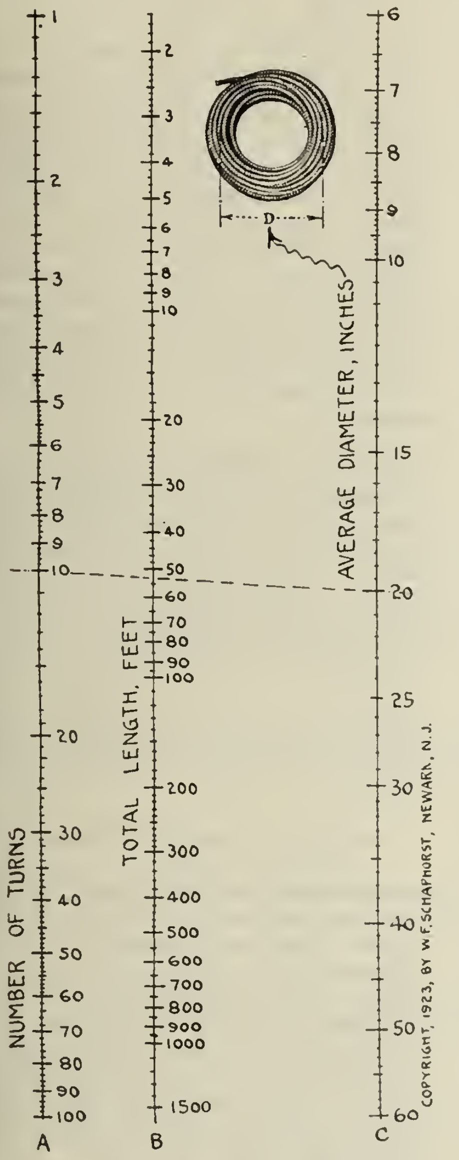
In many cases it will be found that apparently all the apparatus is in proper working order, and of proper size, and in well kept condition, but that oil still gets into the system. This may be due to the use of a poor quality of oil, for it must be borne in mind that practically all oil extractors work on the principle of removing the oil from the steam because the oil, in its solid form, is much heavier than the steam and can be readily thrown out of it by centrifugal force or by suddenly changing its direction. If the oil is of a poor quality it will vaporize at some steam temperatures and will thus be present in the steam as a gas or vapor which the extractors cannot remove. It is important, therefore, that no lubricating oil be used which will vaporize at the steam temperature attained in the engine cylinder. This can be readily tested by making a flash test on the oil in an open vessel and noting the temperature at which it vaporizes, which temperature in turn can be compared with the temperature corresponding to the steam used.

After the cause of oil trouble has been located, it must be borne in mind that frequently the return water will not clear up quickly because of the vast amount of impurities which line the piping, which often takes weeks and months to be washed out. Consequently, the returns should be sent to waste for several weeks until inspection shows them to be cleared up sufficiently to be safely used again. Where it is not desired to waste the water during such a cleaning out period, the system can often be effectively purged by blowing steam through it at intervals, or again the whole system can be flushed out by pumping through it a weak solution of soda ash or caustic soda which quickly cuts the oil from the surfaces.—OTTAWA ENGINEER.

THE LENGTH OF COILS

Very often all of us have coils or rolls of some kind that are to be used for some purpose or other and we wonder how long the rope, wire, cable, hose, belt, etc. might be. We don't like to go to the bother of unrolling or uncoiling simply to obtain the approximate length. The important question usually is "Is it long enough?"

The accompanying chart will be found useful for this very purpose for finding the length in feet of any ordinary roll or coil. All that is necessary is to count the number of turns in the coil or roll and measure the "average" diameter as shown on the sketch in the chart. Then, lay a straight-edge across the chart as indicated by the dotted line. Or, simply stretch a thread across. The answer is immediately found in column B.



For example: how many feet of rope in a coil the average diameter of which is 20 inches and the number of turns 10? Simply connect the 10, column A, with the 20, column C, and the answer is shown in column B as very close to 53 feet.

The range of the chart, it will be noted, is large enough to care for most of the conditions to be found in ordinary practice, ranging from one turn to 100 turns and the diameters range from 6 inches to 60 inches.

The chart can be used backwards as well as forwards. For example: if it is desired to take along a coil of cable containing 300 feet and the workman wants to know how many turns to take, a straight-edge laid across 300 on the middle scale will show how large the coil should be, and the number of turns required in order to obtain the desired length. It is very convenient and quick.—W. F. SCHAPHORST, M.E.

Power Notes

James Paterson, Parliament Buildings, Victoria, B.C., has called for tenders for electrical equipment, for the supply of induction motors, transformers, etc., for the Acute Building, Mental Hospital, Essondale, B.C.

The Universal Oil Burner Co., Ltd., have recently been incorporated with head quarters at Windsor, Ont., to manufacture the Universal Smokeless Oil Burner. The burner is electrically operated and fitted with a safety device. Donald Stuart, the president and chief engineer of the company, is the inventor.

J. Kennedy & Son, Acton, Ont., have received the contract for electrical work in connection with $18,000 theatre being built at Oakville, Ont.

The Standard Paper Box Co., 2724 Park Ave., Montreal, are in the market for an 80 h.p. boiler.

Plans are being prepared for a $30,000 power plant to house seven boilers generating 4,600 h.p. for the Victoria Lumber & Manufacturing Co., Chemainus, B.C.

Plans are being prepared for a substation for the Toronto Hydro Electric System to be erected on the south-east corner of Danforth avenue and Morton road, Toronto.

The Drake Avery Co., 103 John St. N., Hamilton, Ont., have been awarded the contract for heating in connection with the $300,000 power and screen house for the Ford Motor Co., of Canada, Ltd., Ford, Ont.

The contract for the boiler-house to be erected for the Rockwood Hospital, Portsmouth, Ont., has been awarded to McKelvey & Birch, Ltd., 69 Brock Street, Kingston, Ont. Approximate cost $18,000.

The Limerick Electric Light & Power Co., Ltd., with head office at Limerick, Sask., has been incorporated.

The Orillia Construction & Service Corporation, Ltd., Orillia, Ont., has been incorporated and will carry on an electrical installation and heating business.

The firm name of the Ituna Light & Power Co., Ltd., Ituna, Sask., has been changed to the Ituna Electric Light & Power Co., Ltd.

D. Fraser & J. Hawkins, Nelson, B.C., have been awarded the contract for building a new power line from Nelson to Balfour, B.C., at a contract price of $11,200.

J. B. Hamilton, town engineer, Estevan, Sask., has closed a contract with Electrical Engineers, Limited, of Calgary, Alta., for a 300 kw. unit, as an addition to the present power plant. Mr. Hamilton has recommended the purchase of a Skinner Uniflow Engine and a Westinghouse Generator.

The London Cold Storage Co., London, Ont., will install a 50-ton high-speed ammonia compressor, and are asking for prices on same.

The Triumph Machine Co. has received an order for a 20-ton refrigerating machine complete to be installed in the plant of Swift & Co., Regina, Sask.

Among recent shipments made by the Goldie, McCullough Co., Ltd., Galt, Ont., is that of a large heating unit, weighing 14,725 lbs. The machinery and motors are being installed in the new plant of the Norfolk Shoe Co., Tillsonburg, Ont.

The Harbour Commissioners of Quebec have called for tenders for the construction of a cold storage warehouse and power plant in the city of Quebec. Tenders for necessary machinery, piping, electric wiring, sprinklers, etc., will be received separately.

J. H. Harding, Durham, Ont., has received the contract for the installation of a new hot-water heating system in the North Grey Registry Office, Owen Sound, Ont. Work will be commenced shortly.

Tenders are to be asked at an early date by Belleville, Ont., for a gasoline-driven pump of about 3 million gallons capacity and also a pumping station building at a cost of about $25,000. The engineers are Gore, Nasmith & Storrie, of Toronto.

The Quebec Harbor Commission, through Secretary Charles Smith, will receive tenders till Oct. 10 in connection with a $500,000 refrigerator to be built at the corner of Dalhousie and St. James Sts. Tenders will be accepted on the building complete, or on the following items separately: Machinery, including piping; power wiring in the power plant; cooling coils and connections from, and to, the brine coolers; heating apparatus and air condition machines; air ducts, etc.; electric wiring, for lighting of all buildings; elevators in main warehouse; sprinklers in main warehouse and fish warehouse buildings. General Tremblay is the engineer in charge.

Kilgour Bros., of Toronto, are building a $100,000 factory at Windsor Mills, Que. Tenders for plumbing, heating and sprinkler systems are being received by Mr. Prattes, 21 Wellington St., Toronto.

The Canadian Comstock Co. Ltd., Montreal, have been awarded the general contract for a transmission line from St. Jerome to Lachute, Que. The engineers in charge of the work are Beaubien, Busfield & Co., of Montreal.

Wm. I. Bishop, Ltd., Montreal, are the general contractors for a dam and power house on the North River to be built for J. C. Wilson, Ltd., St. Jerome, Que.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

PUMP EXHAUST

IS IT possible for a boiler feed pump lifting its water to exhaust into the suction pipe without destroying the vacuum? If the water is delivered to the pump under pressure will it work satisfactory when the exhaust is piped to the inlet side of the pump?—W. G., Toronto.

Answer:—If you were to pipe the exhaust steam to the suction side of the pump, in all probability it would give you no end of trouble. The exhaust steam would be condensed so rapidly that it would back up to the pump valve, then pressure would build up and force the water back. The net result would be extremely faulty operation of the steam end and continual water hammer.

Pump makers advise keeping the exhaust as free as possible if smooth operation is desired.

The exhaust steam from the pump would heat the feed water about 10 deg.

If you wish to save this heat, the exhaust steam could be piped through a coil in the tank from which the feed water is pumped, or if the water is taken directly from the city mains, a large pipe could be placed around the suction line somewhat similar to the condenser in an ammonia refrigerating plant.

If the water is delivered to the pump under pressure, the troubles mentioned with the water backing up in the steam exhaust line would be worse than when the water is being lifted.

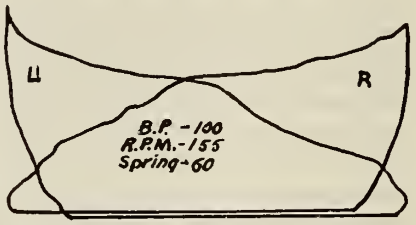
INDICATOR DIAGRAMS

The enclosed card is from an 18x24 *D* slide valve engine, exhausting through a closed heater to the atmosphere. The steam line is five inches and the exhaust six inches.

I would like your opinion of the card, what is the probable cause of the high back pressure and the pressure drop during admission? R.p.m.—155, boiler pressure —100 pounds, spring 60—GEO. G. LEE, Ottawa.

Answer: The high back pressure shown may be caused either by the closed heater or some obstruction in the engine itself. To determine whether or not the trouble is in the heater, exhaust directly to the atmosphere and take some cards. If the high back pressure is then relieved the trouble is in the heater, if not it is somewhere in the engine or exhaust line. In a good closed heater properly set up the back pressure should not be more than from 3 to 5 pounds per square inch.

You do not say whether the engine is governed by throttling or by variation of the cutoff. Cutoff is apparently at about half stroke at both ends of the cylinder. With the simple *D* slide valve cutoff at half stroke makes compression start early. Apparently the early cutoff with high back pressure is causing the steam at the end of the stroke to build up to higher than boiler pressure. The curved admission line is then a result of the pressure dropping back to that of the boiler and possibly to wire-drawing of the steam through the small port area.



The card marked *R* has a very ragged expansion line no doubt due to this end of the slide valve leaking badly.

In the card marked *L*, the expansion line looks very fair.

Both cards measure up only very slightly over 80 pounds per square inch at the point of cutoff. This, however, may be due to throttling by the governor.

A *D* slide valve having the admission and the exhaust controlled by the one valve makes a better looking card when set to show cutoff at about five-eighths stroke, but this does not mean that the economy is any better than with the cards shown.

We believe if you reduce this back pressure, apparently caused by the heater and the exhaust pipe, and look for a leaky valve on one end, you should straighten out some of the peculiarities of the diagram.

USING OIL FUEL

If you have any information or data as to the number of gallons of fuel oil required when burned under boilers to make a ton of distilled water ice, we would greatly appreciate it as we are contemplating changing our 80-ton plant from coal burning to fuel oil.—
—R. SMYTH.

Ans.:—The heating values of coal and oil depend upon their relative compositions. A comparison of the relative heating value of coal and the amount of oil for the equivalent amount of heat is shown by the following tabulation:

B.t.u. per pound of coal	Pounds of Coal Equal to 1Bbl. Oil	Barrels of Oil Equal to 1 Short Ton of Coal
10,000	620	3.23
11,000	564	3.55
12,000	517	3.87
13.000	477	4.19
14,000	443	4.52
15,000	413	4.84

This table shows that if your furnaces consume a ton of coal having a heating value of 12,000 B.t.u. per pound of coal, 3.87 barrels of ordinary fuel oil will have the same heating value. Under general considerations also, the oil burning furnace will operate at a slightly higher efficiency than the coal burning furnace. This is due to the fact that the oil is more readily broken up into small particles and brought into contact with the necessary amount of air for combustion, and that the loss due to excessive air requirements is reduced.

From the foregoing, it will be noted that one barrel of oil will produce approximately from 1½ to 2¼ tons of ice.

The foregoing calculations have been based upon a barrel containing 42 gallons of oil and a weight of 310 to 350 pounds per barrel, and also on the fact that the ordinary distilled water plant will produce from 5 to 8 tons of ice per ton of coal.

These are necessarily general considerations, but will indicate to you the general conception of the amount of oil required.

JOINTS IN AMMONIA WORK

I should like to obtain detailed information regarding the methods in use for making screwed pipe joints tight in ammonia work.—J. THOMAS.

Answer:—The three types of screwed joints used in ammonia work are: 1—the hand soldered, 2—the sweated, and 3—the litharge joint. We believe they are named in the order of their relative value and cost, but good results are known to have been obtained with all, if made as described.

Thoroughly clean the fitting. Thread must be free from grease and oil, and the metal comprising the solder box or recess around the thread in the fitting must be bright. The end of the pipe, about ¾ inch back from the last thread, must be ground or filed so as to show bright metal, and likewise made thoroughly clean.

Next, put some oil on the thread of the pipe and screw fitting or flange on to the pipe, taking care to line up the flange with regard to the location of the bolt holes. Next, set the pipe connection up on end in such a way that the solder box will be level. Expose the joint to at least two flames of torches, blow lamps or Bunsen gas burners, for at least three minutes so as to thoroughly heat up the metal of the fittings and of the pipe. This will serve to burn off any surplus oil.

Burn Off Surplus

While the flames are still playing on the joint, pour in a spoonful of acid. This is the usual acid used for soldering, and is composed of muriatic acid that has been been "killed" or neutralized by the insertion of strips of sheet zinc, sufficient to stop effervescence in the acid.

A soldering hook is found very useful for tinning the joint. This hook may be made of a piece of 3/16-inch round wire about 15 inches long, bent "L" shaped, the leg being about 1¼ inch long and flattened out like a hatchet. Dip the hatchet-end of the hook into a tray containing acid, and from there dip it into a tray containing powdered salamoniac, and work the hook around the joint in the solder box; then take a stick of solder and work that around the joint in such a way that the entire surface comprising the solder box and the bright part of the pipe will be thoroughly tinned. When the entire surface has been thoroughly tinned, the stick of solder may be rubbed around the joint, the heat of the metal causing the solder to melt, and thus gradually fill up the solder box. When nearly filled up, take a piece of lump chalk and rub around the beveled edge of the solder box of the fitting for the purpose of preventing the solder from overflowing, and continue with the stick of solder to fill up the solder box as much as possible, finishing with a smooth fillet.

Now the blow torches may be removed and the point allowed to cool, which will take but a few minutes. Before it is entirely cold clean off the joint with a brush or rag.

"Half and Half"

The best results are obtained by using a thin stick of solder composed half by weight of tin and half lead, a composition which is known as "half and half."

Thoroughly clean the fitting or flange and the threaded end of the pipe, filing the pipe a little way back from the thread so as to show bright metal. If a number of joints have to be made, soldering is facilitated by using a soldering bath composed of 50 per cent. by weight of tin and 50 per cent. by weight of lead, into which the fitting and pipe can be dipped for heating. Otherwise the pipe and fitting will have to be heated by means of two or more blow lamps or torches, and the threads tinned, tinning the pipe about ¾ inch back from the thread, by means of acid and salammoniac the same way as described above, and using a stick of solder.

First, tin the pipe and afterwards the fitting or flange. This must be heated to a high temperature and then screwed on to the pipe as tight as possible without delay, the idea being that the heated flange is expanded by heat, and will practically make a shrink fit. As soon as screwed on and lined up square with regard to bolt holes, if any, fill up the solder box with solder, as already described.

Whenever possible the pipe joints should be made at the bench and not in place, because it is absolutely necessary to have access to all parts of the joint so that one can see and leave no cavities of any kind.

In case of a slight leak the engineer can often reduce same by caulking the joint, but this must be done with the greatest care, and, if possible, with the high pressure off the pipe. To make a joint on a horizontal pipe in place is rather difficult, but may be done by first cleaning and tinning the joint thoroughly, as described, then using an improvised metallic ring held against the solder box and provided with a slot at the top through which the hot solder may be poured in. This expedient might also be feasible in the case of a joint on a vertical pipe in place, the joint being on the underside of a fitting in such a way that ordinarily the solder would flow out. In this case also the joint may be thoroughly cleaned and tinned, and a ring used of "L" shaped cross section, so arranged that hot solder can be poured in from the top.

LOWERS ENGINE SPEED

Without any change of load or alteration of the governor adjustments, why does lowering of boiler pressure result in reduction of speed of an engine?—JOHN DOAN.

Answer: Overcoming the same resistance requires the same m.e.p. to act on the piston. In an engine regulated by a throttling governor and fixed cutoff, the same m.e.p. would require the same average steam-chest pressure, which for lower boiler pressure would not be satisfied except for the larger opening of the governor throttle valve that would be obtained for a slower speed of governor.

In the same manner, lower initial pressure of steam supplied to a cutoff engine would require a later point of cutoff for development of the same m.e.p. which would be satisfied by a governor position corresponding to a slower speed than the shorter cutoff corresponding with higher speed required for higher initial pressure.

On the other hand, with the same load, increasing the boiler pressure results in an increase of speed, for in the case of a throttling governor the engine speeds up until the governor's throttle opening is no more than necessary to obtain the former steam-chest pressure; and in the case of an automatic cutoff governor the engine speeds up until the cutoff becomes short enough to result in the required m.e.p.

EXPANDING TUBE ENDS

Why are the tube ends and nipples of water-tube boilers simply expanded without being beaded over as required for tube ends of fire-tube boilers?—W. HUDSON.

Answer: The object of beading over the ends of tubes of fire-tube boilers is to obtain better protection from the corrosive action of the fire and retain greater resistance against stripping action of the tube-sheet holes.

The ends of tubes and nipples of water-tube boilers are not exposed to the action of the fire, and, if anything, properly performed expanding and flaring without beading has greater holding power, as beading over the ends is likely to produce splitting or disintegration of the material.

CHANGE OVER IMPRACTICAL

An automatic engine has a riding cutoff valve that is controlled by a shaft governor which swings the eccentric around on the shaft. Could the engine be run with a shaft governor operating a slotted eccentric?—E. WYLIE.

Answer: When the governor swings the eccentric around on the shaft, the variation of cutoff is effected by changing the angle of advance of the eccentric and the valve travel is constant.

With a slotted eccentric there would be variation of the eccentricity and variation of valve travel, and consequently a valve designed for constant travel would not be properly operated by a governor controlling a slotted eccentric.

ELECTRICAL TERMS

What are the more common terms used in connection with electric circuits? How can the resistance of a single wire, equivalent to three wires in parallel, be found?—C. A. S. E. MEMBER.

Answer:—The electrical terms in use for circuits are:

AMPERE (I)—The practical unit of current flow is the ampere, which is the current that will flow through a conductor having a resistance of 1 ohm and a potential of 1 volt between its ends. One ampere (direct current) will deposit 0.001118 grams of silver per second from a silver solution.

VOLT (V)—The practical unit of electromotive force (e.m.f.) is the volt. One volt is required to force one ampere through a resistance of one ohm.

OHM (R)—The practical unit of resistance is the ohm, and is that resistance through which the fall of potential is one volt when the current strength is one ampere.

COULOMB (Q)—The unit of quantity of electricity is the coulomb, and is that quantity which passes a cross-section of a conductor in one second when the rate of flow is one ampere.

WATT—The practical unit of power is the watt. One watt is produced when 1 ampere flows under an e.m.f. of one volt.

One kilowatt equals 1,000 watts.

1 watt = 0.00134 h.p. = 0.057 B.t.u. per min.

WATT-HOUR—Watt-hours and kilowatt-hours are the units of energy used in commercial work.

One watt-hour = 2655.4 ft. lb. = 3.412 B.t.u. = 0.001341 h.p.-hr.

For series-connected resistances the combined resistance is the sum of the separate resistances.

For parallel circuits the combined conductivity is the sum of the separate conductivities or

$$\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \frac{1}{R_4} + \cdots$$

The equivalent resistance for three parallel resistances R_1 R_2 R_3 is

$$R = \frac{R_1 R_2 R_3}{R_1 R_2 + R_2 R_3 + R_3 R_1}$$

For four parallel resistances R_1, R_2, R_3, R_4,

$$R = \frac{R_1 R_2 R_3 R_4}{R_1 R_2 R_3 + R_2 R_3 R_4 + R_3 R_4 R_1 + R_4 R_1 R_2}$$

If

$R_1 = 2$ ohms

$R_2 = 3$ ohms

$R_3 = 5$ ohms

$$\text{Then } R = \frac{R_1 R_2 R_3}{R_1 R_2 + R_2 R_3 + R_3 R_1} = \frac{2 \times 3 \times 5}{2 \times 3 + 3 \times 5 + 5 \times 2} = \frac{30}{31}$$

ohms.

Trade Catalogs

The Gates Engineering Company, Ltd., of Montreal, have issued a bulletin entitled Air Cooled Refractories, showing the various materials for boiler settings and furnaces handled by them. The Gates air-cooled suspension arch, for use with chain grate stokers, waste fuel furnaces for burning tan bark, hot fuel and sawdust, air-cooled furnace blocks, interlocking fire-box lining, in which a lug at the back of each brick holds the block solid instead of the use of cement; boiler door arches and jambs, and rear combustion chamber arches, are described in detail.

Bulletin No. 117 of the Uehling Instrument Co., of Paterson, N.J., represented in Canada by the Combustion Engineering Corporation, illustrates, in diagrammatic form, the simple principle of operation of Uehling CO_2 recording and indicating equipment. This equipment is unlike all other CO_2 recorders in that it has no moving parts and employs no chemicals in liquid form. Instead, it operates on a simple scientific principle based on varying gas tension between two orifices. Of rugged construction, the equipment is designed to meet all power plant conditions.

Convention Notes

The annual convention of the National Association of Stationary Engineers was held in the Broadway Auditorium at Buffalo, N. Y., Sept. 11 and 12. Booths exhibiting equipment and supplies used in a power plant, were arranged in splendid order. Lattice work partitions separated each booth, which was very effective from an artistic point of view as well as being economical. The sessions while thorough were conducted from the standpoint of economy of time.

The Question of the revision of the constitution was dealt with by means of a referendum vote. Among other matters, the question of buying coal on a B.tu., or heating value basis was turned over to a committee for further investigation.

The following are officers of the Canadian Electrical Association, appointed for 1923-1924:—President, P. T. Davies, commercial manager of the Southern Canada Power C., Montreal; vice-president, J. E. Woodyatt, general manager, Southern Canada Power Co., Montreal; vice-president, J. E. Woodyatt, general manager, Southern Canada Power Co., Montreal; vice-president, R. J. Beaumont, manager of subsidiaries, Shawinigan Water & Power Co., Shawinigan; treasurer, C. Johnstone, auditor, Southern Canada Power Co., Montreal; secretary, Louis Kon, manager publicity department, Montreal Light, Heat & Power Co., Montreal.

The N.A.S.E. is still holding its own from a membership standpoint, having about 20,000 members in good standing. A special committee is dealing with the educational program, but discussion on this subject revealed the fact that only a small percentage of the engineers avail themselves of this opportunity to improve their education. The membership drive was very disappointing, and it was agreed that steady work and gradual increase alone brought results.

F. Martin, of the National Board of Fire Underwriters of New York, spoke to the Association on "Preventable Fire Losses an Alarming and Criminal Economic Waste." He also explained the elements of success by giving a new interpretation of the words "Enthusiasm," "Ambition," and "Application." Slides were used to illustrate the points referred to by Mr. Martin, showing recent losses of life and property in Canada and the United States.

Five years ago the N.A.S.E. loaned to the C.A.S.E. several sets of slides for educational purposes, which have been in circulation in Canada ever since. At the recent convention they offered to exchange these slides for others which they believed would be of more use to-day to the C.A.S.E.—GEO. J. SOUCY, Executive Secretary, C.A.S.E.

Construction

Dunkley Baby Car Co. of Canada, Ltd., Ford, Ont., has been incorporated to manufacture and deal in conveyances and vehicles of every kind, and accessories and parts, with $50,000 capital, by William H. Dunkley, Birmingham, England.

The Montreal Harbor Commission is building a machine shop to cost about $40,000.

The Municipal Electric Light and Power Co. plant at Melville, Sask., was damaged by fire with a total loss of about $100,000.

Equipment will be purchased soon for the new plant to be erected at Collingwood, Ont., by the Canadian Postal Locknut and Bolt Co.

The Alberta Granite and Marble Works, Edmonton, Alberta, will erect a factory to cost $10,000, and will instal additional equipment.

Plans are being revised and new bids called for the erection of a foundry for the Canadian Westinghouse Co., Aberdeen Ct., West, Hamilton, Ont.

The Yorkton, Sask., Power Plant will build an addition costing approximately $75,000, and will instal two 300-horsepower engines and two generators.

Moore Bros. Machinery Co. Ltd., has been incorporated to deal in and manufacture mill supplies and machines at Montreal, Que., with $40,000 capital.

Among the recent incorporations in the Province of Quebec, is the Ottawa River Power Co., Ltd., head office at Hull, Que., and with a capital of $450,000.

Continental Motor Services, Ltd., has been incorporated for $100,000 to manufacture and deal in automobiles, gas engines, flying machines, and accessories, at Toronto.

The Vipond Consolidated Gold Mines, Timmins, Ont., are increasing their mill capacity to 150 tons, and it is understood additional electric equipment is required.

The Continental Equipment Co. Ltd., Montreal, Que., has been incorporated to manufacture and deal in electrical machinery, motors, dynamos, etc., with $25,000 capital stock.

The Thompson Enterprise Co. Ltd., Toronto, Ont., has been incorporated to manufacture floor polishing machines, electrical machinery, equipment, etc., with $40,000 capital stock.

The Stalker Engineering Co. Ltd., has been incorporated to carry on a business as iron founder, mechanical engineer and manufacturer of machinery, at Simcoe, Ont., with $40,000 capital stock.

The Ottawa River Power Co. have completed plans for development at Bryson, 50 miles above Ottawa. The first installation will be one unit of 25,000 h.p. The transmission line to Ottawa is expected to be completed by October 15.

The Essex Border Utilities Commission is having plans prepared for the construction of a filtration plant at Ford, Ont., to serve five municipalities at an estimated cost of $150,000. Bids will be received about Nov. 1. J. C. Keith, 300 Ouellette Ave., Windsor, is the engineer. The owner is in the market for materials and equipment.

Comments in the Power Plant Field

"A Degraded Certificate"

The Editor, Power House:

I have just had my attention called to a letter published in your valuable medium, "Power House," in answer to my letter in the issue of August 20, on "Examination Tactics."

If your readers will give my letter the "twice over" they will see that my criticism was timely and to the point, for not only does Mr. J. M. Brown fail to justify the variable standards of examination, but he hands out a new basis of standardization by suggesting that "the diligent and proficient should have the preference" in advancement, instead of the "tried and true with a long service record," who are more competent to exercise judgment and more efficient in the long run, although perhaps lacking somewhat in book knowledge.

Increased knowledge is a good thing, but the safest thing for our national industries is to set a standard requiring a certain amount of general experience to counterbalance a large fund of general knowledge.

There have been cases where men granted the higher grade certificates have never had charge of a plant, some being only firemen in a heating plant.

"Dominion Wide" or a uniform Interprovincial certificate is what the stationary engineer wants, patterned after the Interprovincial Regulations for Boiler Inspections.

By these regulations, no province suffered, no boiler inspector was inconvenienced, and no manufacturer has so far complained. In fact all are better satisfied because a big subject was handled in a big way and not in the "provincial" way of the Ontario Engineers' Certificates,with exceptions and special privileges.

I would like to know how well the Ontario Stationary Engineers Act has been enforced since 1918. I am sure the supply of certificates has greatly exceeded the demand, at least, for second-class engineers. —GEO. A. BROWN, 659 Markham Street, Toronto.

SOME NEW THEORIES

In the June 20 issue of Power House, W. H. Casmey, in telling us how to save millions of tons of coal yearly, propounded some new theories which Canadian engineers ought to consider well as to their correctness.

Mr. Casmey says that it is the oxygen combined with the coal which results in the evolution of heat. Oxygen combined with coal or carbon gives carbon dioxide.

I have always understood that combustion is the rapid chemical combination of carbon and oxygen, or of hydrogen and oxygen. Possibly Mr. Casmey means that it is the act of combining which produces heat.

Further on in his article he states that "the only effect of the introduction of too large a quantity of air is to cool the furnace below the point of combustion." I presume that by the point of combustion he means ignition temperature. As the ignition temperature of carbon from bituminous coal is 766 deg. Fahr., and 925 for carbon from anthracite, it is hardly likely that the furnace temperature will be lowered below that point, in practice, even wasteful practice.

Increases Temperature

It is generally admitted that excess air, while lowering the furnace temperature, increases the exit gas temperature, thereby producing waste.

It is also accepted as correct that excess air by acting as a dilutent reduces the density of the smoke. This can be proved by leaving the furnace door open after firing and noting whether the smoke is as dense as it is when the doors are closed.

Another New Theory

Another new theory is that the reason that we use excess air is to make the temperature of combustion suitable for steam raising purposes. A common notion among engineers is that excess air is supplied for the purpose of securing complete combustion by mass action of the gases. With proper mixing devices, or a furnace so designed that good mixing results, a lower percentage of excess air is possible.

It is taught in our schools that for the perfect combustion of 1 lb. of carbon, 11.52 lb. of air, containing 2-2/3 lb. of oxygen and 8.85 lb. of nitrogen, are necessary. Mr. Casmey disagrees with this, claiming that 12 lb. of air are necessary for 1 lb. of coal, and that this air contains 2½ lb. of oxygen and 9½ lb. of nitrogen. As there is no coal containing 100 per cent. carbon, the weight of air per lb. of coal is less than 11.52 lb., being as low as 7 lb., with some samples of coal.

Mr. Casmey then asserts that low temperature, as a result of adding fresh fuel, will produce smoke. but we know from experience that high temperature will also produce smoke when fresh fuel is added. It is not clear how he arrives at the conclusion the 11 per cent. of the coal is lost up the chimney with black smoke. A. D. Pratt says "the direct loss from unconsumed carbon passing off in this manner is probably rarely in excess of 1 per cent. of the total fuel burned. even in the case of the blackest smoke."

Burn Coal Smokelessly

He also says that a smokeless chimney is not necessarily indicative of proper or even good combustion. Large quantities of excess air in diluting the products of combustion naturally tend toward smokeless stacks. Jas. W. Hays says that to burn coal smokelessly is a simple matter.

L. P. Breckenridge, who is considered an authority on combustion, declares, "the absence of smoke by no means indicates perfect combustion. It may simply mean excessive air dilution, and this means uneconomical operation."

Statements are frequently seen to the effect that one-quarter or one-third of the fuel burned goes off in black smoke from the chimney. It is doubtful if the black carbon particles which issue from chimneys, and which we call soot, ever amount to one per cent. of the fuel burned in any furnance. The appearance of black smoke is fortunately the signal of incomplete combustion, and the losses due to this cause are many times the losses due to the carrying away of the small soot particles.

Mr. Casmey hands the firemen a vicious slap when he says: "A smoking chimney announces to the neighborhood that the man at the fires is either ignorant or neglecting his duties." I will leave the fireman to defend himself, but when you consider the time and money spent in experimenting with different designs of furnaces and stokers it would almost seem as if furnace design had something to do with smoke production.

Damage to Buildings

Besides the loss due to incomplete combustion, which may be serious enough, there is a far greater loss, and the pity of it is, that the plant producing the smoke is not the one paying for it, and that loss is the damage to buildings, increased artificial light, made necessary by the decreased amount of sunlight, increased laundering and cleaning, and damage or injury to vegetation. Across the lake. in Cleveland, Ohio, this damage amounts to $12 per capita per annum, it is said.

Mr. Casmey, however, ably propounds one theory, with which I think many engineers will agree, when he says: "In making steam, the cost of which is the foundation of practically all manufacture, chaos, as a rule, reigns." He does not give the cause for this "chaos," so I may, in a subsequent contribution, give the opinion of a few authorities thereon.

I have cited a few instances in which Mr. Casmey, able engineer as he is, disagrees with views commonly held by engineers, and I would like to hear what other engineers think on the matter.— ROBERT McLAREN, Chief Engineer,
160 Dovercourt Road, Toronto.

BOILER COMPOUNDS

Noting that a fellow engineer has written to Power House asking if the boiler compound formula I mentioned on August 5th, would be suitable to his conditions, I now submit the following.

The water used in all Toronto plants is practically uniform and does not necessarily need to be analyzed to ascertain what kind of compound should be used, for that which has given good results at a plant in West Toronto should give equally good results in a Queen St. or Dupont St. plant providing the operating conditions are about the same. If the operating conditions differ it does not mean that a change of compound is necessary but that the quantity used should be altered to suit conditions.

For instance, if you are using a large quantity of returns and little raw water for make-up, it is not necessary to use as much compound as if you were using no returns. If no make-up water is used at all it would be better perhaps to do away entirely with the caustic soda. In any case the amount of caustic used should be reduced.

The formula is not of my invention but it has been used for some years in the plant where I am employed. As I did not like following in the footsteps of my predecessors without knowing what I was doing, I asked Power House for information on the subject and after reading same, I altered the formula to sixty pounds sal soda, four pounds caustic soda, four pounds Japonica, two pounds Irish Moss, two pounds manganese dioxide. Since using this I find, upon washing out the boilers, that there is considerably more mud and not so much scale as before.

The quantity of compound to be used and the method of feeding same, can best be found out by experiment. I use one quart of the above mixture per 100 h. p. per nine hour day and have been feeding it for the past nine months through the feed pump, putting the required amount in one injection. Recently I have commenced feeding it continuously throughout the nine hours.—E. GOLIGHTLY, 8 DENTON AVE., EAST TORONTO.

QUEER IDEAS

My work takes me into many power plants, and I have found some of the ideas used by the workmen, to say the least, rather queer. It hardly seems possible that some of the things I have seen could really exist in a power plant.

In one plant which contained five return tubular boilers, 66 inch by 16 feet, the connections of the steam pipe were so rigid that the vibrations from the engines were directly communicated to the boilers, which trembled and shook in a nerve-destroying manner. When I spoke to the boiler-room operator about it, explaining that there was practically no provision for expansion on the line, and that a wreck could be expected at any hour, they merely laughed and told me that the plant had been operating without accident for years, and was good for many years more. It seemed to prove the truth of the saying "Providence protects the ignorant and the foolish."

While visiting another power plant in the country, I noticed a neat pile of green oak branches cut into lengths three or four feet long, and from four to six inches in diameter. During the course of conversation with the man in charge of the plant, he informed me rather proudly that the green timber had all expensive compounds for the prevention of corrosion "skinned a mile." It seems that he cleans out the boiler once a month, and puts two or three of the lengths of wood in it on top of the tubes, removing the ones he had put in the previous month. The chemicals boiled out of the wood during the month's run prevented the formation of scale, and he claimed his boiler to be the only one in the neighborhood entirely free from scale and corrosion. It, of course, is possible that the tannic acid or other chemicals in the green wood would act as he claimed.

In a third plant I found a budding inventor who had packed the boiler feed pump with an oil soaked cloth so attached that the plunger got a rub from it at every stroke. He said he found the pump working easier and the packing lasting longer. Another "expert" connected a water pipe to the lubricator condenser, his idea being to get a quick flow of oil anytime he wanted it.

Many schemes discovered in plants remote from settled districts could likely be recorded by many readers of Power House, which would be just as strange as the foregoing.—JAMES E. NOBLE, 173 Macdonell Ave., Toronto, Ont.

C.A.S.E. ENQUIRIES

To the Editor, Power House:

Letters are coming in from all over the country enquiring how to become members of the C.A.S.E. Invariably I learn that this interest has been created through the C.A.S.E. Notes appearing regularly in the columns of Power House. The majority of the writers indicate that their chief interest is to obtain the advantages of practical education in their chosen field. I will quote from one writer, which is more or less representative of all the correspondents.

"I read with interest the C.A.S.E. notes appearing in Power House, and wish to assure you that my best wishes are with your association in the matter of their educational campaign. I sincerely believe that it would be to the credit of any operating engineer to be a member of such a society, especially when you consider that it offers a free medium for the exchange of ideas and thorough discussion of the problems of our chosen profession, and in consequence to know that you will receive a genuine practical solution. Kindly furnish me with full information as to how to become a member of this association, or how I can go about organizing a branch in our vicinity."

As this question is of interest to many of your readers, I presume you will permit me to furnish a brief outline for publication.

I will take for example, the engineer who writes in from Port Colborne, and requests information similar to that previously stated. The writer, in addition to enquiring how to become a member, the cost to join, and how to organize a branch, desires to know how he can get a copy of the answers to the list of questions published in Power House, in connection with last season's C.A.S.E. educational program. This goes to show that the majority of the engineers want to know and learn the answers given by competent and practical men to their every-day problems.

Briefly, the constitution states that when seven or more engineers (of any district) make application for a charter, the Grand President, having made enquiries as to their character and qualifications, and upon receiving a favorable report, will instruct the executive secretary to forward the charter to the applicants, upon the receipt of $25.00, and other necessary equipment and supplies to start a new branch. The outfit consists of two gavels, five rituals, twelve copies of the constitution, writing paper and envelopes, due cards and application cards, as well as the charter. Branch seals are extra, but furnished at cost.

The association is devoted to the promotion of educational, professional and engineering knowledge, thereby fitting its members for better and higher situations, and to maintaining the rights of the engineering profession; and for the transaction of any business that may be legally brought before it; also to the securing of the enactment, enforcement and unification of engineering laws throughout Canada.—GEO. J. SOUCY, 48 Moore Ave., Toronto, Executive Secretary.

Miscellaneous

Among the Federal incorporations of business gazetted this week are the following:—The Engineering & Inspection Co., Ltd., head office at Toronto, capital, $50,000; the Tidiout Refining Co. of Canada, Limited, head office Montreal, capital $200,000.

The Gates Engineering Co. of Montreal has just recently installed one of their Flat Suspended Air Cooled Arches, sixteen feet long by eleven feet wide, under a 500 h.p. unit in the Frasers Limited Power Plant at Edmundston, N. B. This Dutch Oven was built purposely for burning hog fuel and mill refuse, and is developing continuously 1,000 to 1,100 h.p. with fuel up to fifty per cent. moisture.

A. E. Rule, known in the power plant field as "Golden Rule," the man who did the bricking in of the boilers in the Royal Coliseum, Canadian National Exhibition, says that there is a great deal of activity in his line of business and that many power houses are having extensive repair work done on the boiler settings, especially on the furnace arches.

Montreal Tramways, Montreal, Dwight P. Robinson & Co., consulting engineers, have just purchased from the Combustion Engineering Corporation, Limited, for use in conjunction with 2–1,200 h.p. B. & W. boilers, 2 self-contained Type C. travelling grate stokers, 16 ins. wide, and 17 ft. 6 ins. long, each capable of burning sufficient coal to develop 300 per cent. of the boiler rating or 3,600 h.p. per stoker, it is claimed.

The stokers are the largest of their type in Canada and are similar to six recently purchased by the City of Birmingham, Eng., for the new Nechells Power Station.

One of several unique features in this installation is that the stoker driving mechanism and the forced draft fans with their air ducts are incorporated as part of the stoker, the fans being mounted one on each side of the coal hopper. The fans are direct motor driven. This feature eliminates air ducts in the boiler setting.

Progress in New Power Equipment

A NEW SUPERHEATER

THE superheating of steam is now attracting a great amount of attention, not only in power station work, because of rapidly increasing boiler pressures, but also from the ordinary industrial steam user.

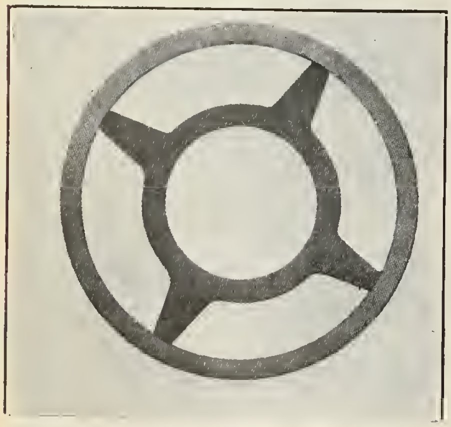
The benefits of superheating, both from the point of view of reducing the steam consumption of engines and turbines, and also in thoroughly drying the steam so as to reduce condensation losses in the pipe circuits, are so obvious that it is extraordinary the majority of industrial steam users have failed to realize the advantages to be obtained.

One of the latest developments in the science of superheating, is that Daniel Adamson & Co., of Dunkinfield, near Manchester, England, have produced a sectional modification, known as the "A.B. Sectional Type," of their accumulator superheater.

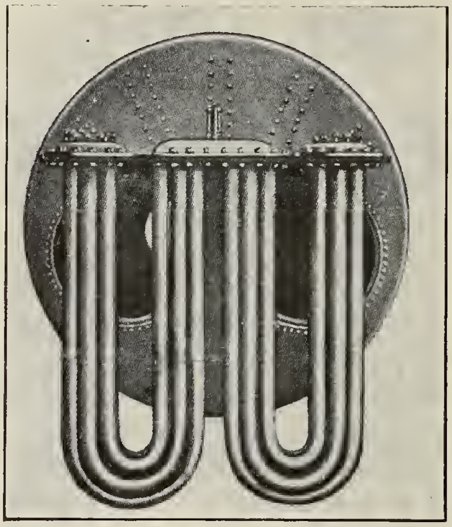
Split Steam Up

The essential principles of the design of the standard "Adamson" accumulator superheater consist in the use of specially heavy and large diameter (four inches) mild steel seamless tubes quarter inch thick, bent in the form of the usual simple loops suspended in the flames and hot gases, with an internal cast iron gilled core in each of the straight legs, so as to split the steam up into five separate portions during its passage through the tubes.

As a consequence the heat transfer to the steam is very efficient, each of the four outer divisions or portions of the steam, very narrow in width, being heated by the body of the steel tube, whilst the steam in the fifth and inner central division is heated from the cast iron core, which is touching the outer steel tube at a number of points, as well as being kept hot by the partially superheated steam in the four outer divisions. The five streams of superheated steam re-unite at the bottom in the loop portion of the tube, and split up again during the upward passage in the second leg, the bend being a simple tube without any internal gilled core, and the superheater is so arranged as to be in two separate divisions of loops, the steam passing first through one set of loops and then through the other, so that it is split up into five parts and re-united again four times in its entire passage through the superheater.



Section of tube with view of internal accumulator core.



View of superheater at the back of a Lancashire Boiler.

The inner cast iron gills or divisions are of course not subjected to unequal pressure and as they are of massive construction they store up a large amount of heat, acting as heat accumulators, thus avoiding the fluctuations in temperature characteristic of many types of superheater, a very important point.

Expanded at Each End

The four inch steel tubes are expanded at each end into circular top headers made of $1\frac{1}{4}$-$1\frac{1}{2}$" rolled steel slabs, with seven-eighths inch hydraulically pressed mild steel cover plates, the equipment also including a spring loaded safety valve, two thermometer sockets, and a heavy cast iron carrying frame with two eye-bolts to fit into the brickwork above the downtake of the boiler.

A number of advantages are claimed for this design, including strength, simplicity, outer flanged joints only, the doubling of the heating surface because of the internal accumulator core tubes, the thorough mixing of the steam and even superheating, together with efficiency of the heat transfer, and the equalizing of the temperature on the accumulator principle already mentioned.

The new "A. B. Sectional" modification retains these essential features, but in addition, any tube can be withdrawn, replaced, or blanked off, or an additional tube installed or withdrawn in a few minutes, whilst the parts are easily handled and packed for shipments, and the entire superheater can be put together actually in the boiler downtake, since the sections can be passed through very small openings.

COAL STORAGE

During warm weather and periods of light demand, such as August, mines have ample time to fully prepare coal. Washing, picking, sizing and other processes are carried forward as they should be and the finished product is in every way up to standard. Winter sees the mine rushed with orders. Under such circumstances it is almost impossible to maintain the same high standard of coal that exists during summer. This often means more to the consumer than is realized. Poorly prepared coal contains slate, bone and other elements that contribute largely to the ash content. And the greater the ash content, the more expensive the heat obtained.

Eliminating the seasonal element will stabilize the industry, improve preparation, aid production and help distribution. This bettered business practice reflects itself in prices, not only favorably to the consumer but to the miner, the operator and all concerned.

The storage of coal with the average industrial user is largely a matter of facilities. And because of this there are, here and there, factories that find it impossible to store coal. We are prone to look at "big" examples in everything, however, forgetting the smaller and more ordinary things. Perhaps because of this habit, those who are in a position to store coal hesitate doing so because of the erroneous belief that large investments and complex systems must be made.

In the discussion of ways and means of storing and reclaiming coal, Link-Belt, Limited, prepared the following plan which included a standard portable belt conveyor for unloading and storing the coal in the space available. This plan was adopted and a 31-foot machine was installed and put into operation. This conveyor, at an agle of 30 degrees will pile 13′6″ high, but as is shown in the drawing, the conveyor is lowered so that it piles but to a height of eight feet. This prevents burying the wheels. The machine was made to pivot, which enabled it to serve an arc about 36 long, with a minimum handling of the machine. Thus an 8′ pile 36′ long gives a storage of about 70 tons. The drawing shows how the portable belt conveyor backs away from the pile as the coal is stored out.

In actual operation this plan and equipment, it is claimed, worked out somewhat as follows:

Cost of handling coal:

Fixed charges per year:	
Depreciation at 20% (conservative)	$208.20
Interest, figured on an average investment of $521 at 6%	31.26
Upkeep per year	50.00
Electric current	25.00
Total	$314.46

Boiler Setting
Service

THE Gates Engineering Co., Limited, are in a position to contract for and specify on all boiler brick work with the least possible delay. Our Engineering Department is qualified to look after your interests, having made a close study of Combustion Problems.

Our Motto—Service and satisfied clients. The confidence of those who use Gates' Patented Air-Cooled Arch, etc., is unqualified, and is retained, because of the low maintenance cost and the guaranteed results.

314 Notre Dame Street W., Montreal

PRATT & CADY VALVES

P. & C. Swing Checks are made in the regrinding type and with renewable asbestos, rubber or leather discs. They have a full port opening and may be used in either the vertical or horizontal position.

The Swing Type of check valve was first patented by Pratt & Cady in 1878.

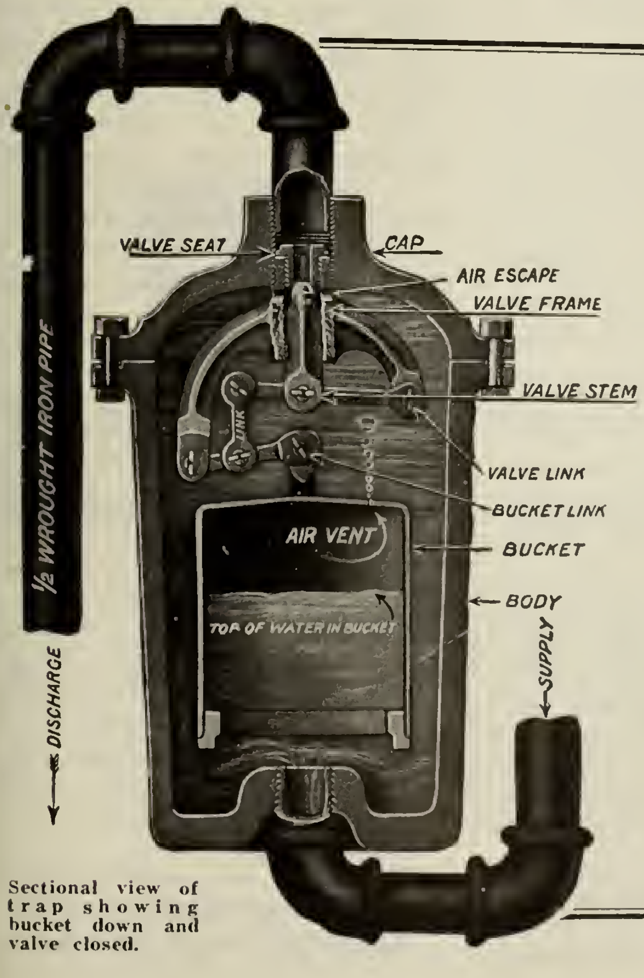
CANADIAN REPRESENTATIVES—CANADIAN FAIRBANKS-MORSE CO., Montreal, Canada.



Sectional view of trap showing bucket down and valve closed.

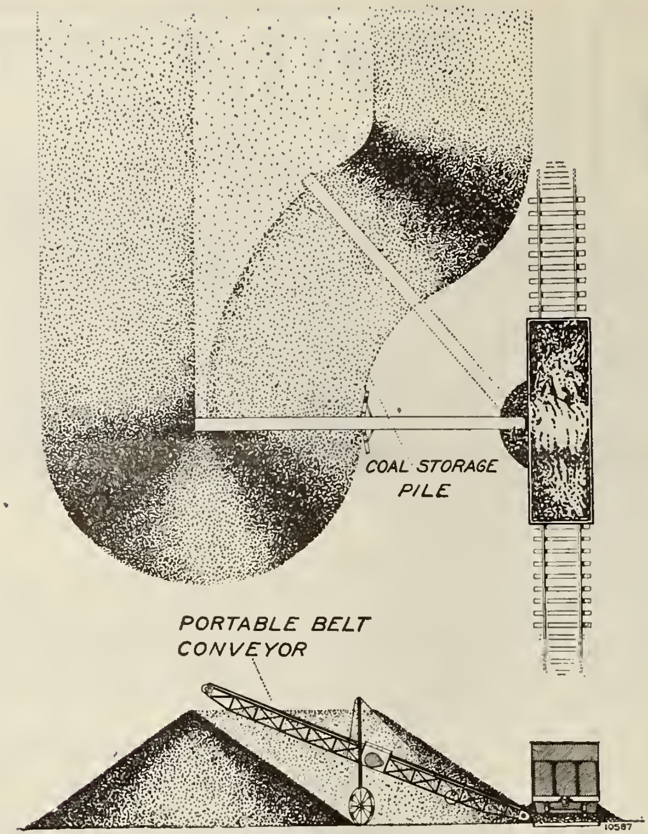
Armstrong Steam Trap

The Armstrong Steam Trap, in principle, is different. Its patented method of opening and closing the valve through the powerful leverage and positive action provided by an inverted, submerged bucket is unlike that of any other trap made.

That this simple principle has brought a difference in steam trap service—a greater reliability and a lowering of maintenance costs — is being proved by thousands of traps that have given hardly a moment's trouble since the day they were installed.

Let us send you full details.

The Arthur S. Leitch Co., Limited
High Grade Power Plant and Pumping Equipment, Engineering Specialties
1001-2 Kent Bldg. - Toronto



Showing method of handling coal from cars to storage pile. The arc shown in the side elevation is 36 ft. long, and has a capacity of about 70 tons (piled to a height of 8 ft.).

Labor charges when handling coal by portable belt conveyor, based on 4,500 tons (assume 90 cars) 10 hours per car at 40c per hour	360.00
Total	$360.00
Total cost of handling coal	$674.46
Or about 15c the ton.	

Compared with these figures, the cost of handling by hand, using 40c per ton for 4 500 tons, we have a total of $1,800.00, which equals a saving, it is claimed, of something over $1,100.00 in favor of a conveyor.

BOILER FEED WATER EVAPORATION

(Continued from page 30)

to the evaporator heater, from which the air escapes to the atmosphere as shown.

Fig. 3 illustrates an arrangement in which low-pressure exhaust steam is used in a specially designed evaporator, the vapor from which passes into the evaporator heater, through which the main condensate is discharged. The condensate is then passed into another heater where it is raised in temperature by exhaust steam, and then flashed in the de-aerator, in which a vacuum is maintained by a steam-operated ejector, which also serves to maintain a vacuum in the evaporator heater and consequently in the evaporator flash chamber.

The steam ejector discharges into the exhaust steam heater, and all drains are led into the de-aerator, the air escaping into the atmosphere.

In these arrangements the make-up consists entirely of distilled water, and all water must pass through the de-aerator before it is delivered to the boilers. Further, all heat is utilized for feed heating, and, wherever possible, the heating is done with low-grade steam from which energy has been abstracted.

ELIMINATING GRUNTS

(Continued from page 28)

and flows through the outlet passage into the steam pipe.

Subject to Pressure

From this it is clear that the oil in the body of the lubricator is subject to the pressure of the column of water extending through the small tube inside of the body, and the pipe P. If the steam pressure is 80 pounds per square inch, and the pressure due to the column of water is, say, one pound, the total pressure is eighty-one pounds. Liquids communicate pressure equally in all directions, therefore the oil in the body of the lubricator will press in all directions with a force of eighty-one pounds, but where the oil rises to the surface of the water in the sight feed glass, a force of eighty pounds back pressure is encountered, and since the steam pressure is practically the same at S and S, Figure 2, these forces neutralize each other, and there is left the pressure of the water or hydrostatic head extending through pipe P.

There is some back pressure due to the short column of water in the sight feed glass, but this is so small that it may be neglected, since this pressure is always less than the pressure on the oil in the body of the lubricator. Therefore, the oil as it leaves the feed nozzle, in the form of drops, is no longer acted upon by the pressure in pipe P, and rises through the water in the sight feed glass from the force of gravity because the oil is lighter than water.

It makes no difference whether the steam pressure is eighty pounds or only ten pounds. This is the reason the lubricator feeds as well when connected as shown in figure 2 as when connected to the steam pipe as usual, so long as the column is high enough to produce sufficient pressure in pipe P.

This arrangement is not a new idea and is used when it is not convenient to connect lubricators to vertical steam pipes, as, for example, in a case where the steam pipe must be brought up through the floor and led to the steam chest in a horizontal direction. In such cases the lubricator may be connected to a column located between the throttle valve and steam chest.

POSITIONS WANTED

FACTORY SUPERINTENDENT—OR CHIEF Engineer is open for engagement. Have had wide experience in operating power plants and handling help in Canada. Apply Box 107, Power House.

EQUIPMENT FOR SALE

NEW AND USED MACHINERY AND SUPplies; get our prices for machinery on monthly rental. Apply Box 113, Power House.

PIPE THREADING TOOLS—"TOLEDO" AND "Jardine" are the best; catalogue P-3 tells you; all sizes up to 12-inch at one cut by one man. A. B. Jardine and Company, Limited, Hespeler, Ontario.

PIPE AND BOILER COVERINGS—ENGINE packings. Apply Box 111, Power House.

SAWMILL MACHINERY MANUFACTURED by sawmill machinery specialists. Apply Box 115, Power House.

SAWMILLS PORTABLE DOUBLE EDGERS; also all kinds of sawmill machinery. Apply Box 116, Power House.

BUSINESS CHANCES

SMALL BOILER REPAIR BUSINESS FOR SALE—with house property adjoining. No opposition. Located in a large manufacturing city. Reason for selling, owner in ill-health. Apply Box 110, Power House.

PISTON RINGS

EVER-TYTE and ZELCO Piston Rings with Patented Zelco Process save Gasoline, Oil, increase capacity, prevent cylinder from wearing out of round, lessen carbon; after using, make arrangement with us to sell them; made up to 80-inch; used in locomotives, boats, engines, compressors, ice machines, autos, trucks, tractors, etc.; are looking for distributors with mechanical knowledge; all or part time; real opportunity. Ever-Tyte, St. Louis, Mo.

A Striking Message

A STRIKING message to manufacturers of power-house equipment is derived from a letter written by a "Power House" reader in reply to a request for a criticism of the paper and for suggestions as to how it could be improved. Here is the letter:

"I believe Power House compares favorably with other power-house journals in many respects. One department I would like to see at least three times its present size is the selling section. Many of the ads. are from all-American U.S. firms but there must be many others, some of them with Canadian branches and agencies, who do not carry an advertisement in Power House. **This is a mistake on their part, but for all I know to the contrary** it may be due to the lack of energy on the part of the Power House ad. manager in getting after them. **It is an absolute fact that the engineer is more than ever dependent upon his technical journals for information in connection with new ideas in power plant equipment. He does not depend upon the reading pages SO MUCH AS ON THE ADVERTISEMENT PAGES."**

Every Engineer, Mechanic and Electrical Worker will welcome this new master set. It will answer your problems.

It will help you with your daily work.—A sure source of advancement and higher pay. Complete up-to-date information that is thoroughly and easily explained on every branch of modern engineering and electrical practice.

A book that can end furnace trouble

THIS new book will tell you how any man about the plant can install Plibrico Jointless Furnace Lining to resist temperatures to 3,100 deg. F. — to cut down the loss of heat through the setting — to give two, three and even four years' service without relining.

The knowledge gained can end the continual replacement of furnace linings that so many power plant operators find necessary. Every Canadian engineer should read it.

Do you want your copy? Just send a post card. No charge—no obligation.

PLIBRICO FURNACE LINING

REFRACTORIES and FURNACE DESIGN
A complete treatise on the building of furnaces

MAGNOLIA ANTI-FRICTION METAL

is always uniform in composition and dependable in service. It adapts itself quickly to rough or scored shafting, makes smooth highly polished contact surfaces and "sets" particles of grit where they cannot cut the journal or appreciably increase friction.

Magnolia Metal melts and pours well, is easily peened and scraped in and is perfectly adapted to a very wide range of speeds and pressures. With the lowest frictional coefficient of any known bearing metal, it runs cool with less lubricant and is excellent protection against hot boxes and melting out where lubrication is neglected.

PRACTICAL ENGINEER POCKET BOOK

Over 600 Pages.

A valuable reference work imported from England and sold as an advertising medium at the low price of 50c. post paid—less than the actual cost of importation.

Address New York Office.

Safety Plastic

METALLIC PACKING

Self-Lubricating
Practically Frictionless

In Cotton Tubes

Made of an alloy of the finest anti-friction metals, and the best lubricating materials which always remain in the packing; we have records to show that it has been in constant use in many engines, pumps, compressors, expansion joints, valves, etc., for over 12 years, giving consistent satisfaction.

Packing in bulk.

GUARANTEED TO LAST THREE YEARS WITHOUT RENEWAL.

Let us send you further interesting details also about our "Safety" Superheat Sheet Packing.

Building a one-piece furnace lining without special forms.

BETSON'S
TRADE MARK
PLASTIC FIRE BRICK

Makes practicable, solid, one-piece furnace linings, including front and back arches, side walls and baffles. It costs but little to install in any make or type of boiler. It saves fuel, annoying shut-downs, costly repairs, and increases the amount of power from the fuel used.

Complete details of the many uses, methods of installing, how to order, measurement blanks, etc., are contained in a booklet of information which we will gladly send you. Tell us the individual to whom it should be addressed.

DRY STEAM

Under All Operating Conditions With the

ANDERSON STEAM SEPARATOR

The Anderson Steam Separator is a positive protection against engine break-downs because it delivers dry steam under all operating conditions. The moisture is completely separated by the combined action of centrifugal force and the sudden reversal of high velocity steam current—the moisture cannot be picked up again.

TAKE YOUR TRADE PAPER INTO PARTNERSHIP

BY R. LEE SHARPE

(In Inland Printer)

By jimminy, I get peeved the way some business men treat their trade journals. They render an invaluable service in their special fields. They promote efficiency and economy. They offer information which can not be secured elsewhere. They work in season and out of season for the special field to which they are devoted. *They usually reflect the very best of the industry they serve.*—Evan Johnson, Editor "Office Appliances," Chicago.

"WHEN I took my trade paper into partnership, prosperity seemed to come my way," said a successful business man recently. Let him tell the story: "When I first began business I treated my trade paper with that indifference usually accorded a stepchild — until one day I suddenly 'woke up.' It was near the close of a warm July afternoon, and in my haste to get rid of details to leave for home, I tossed the current issue of my trade journal at the waste basket. It missed its mark and fell open on the floor. In stooping to place it in that ever yawning receptacle my eyes caught the heading 'Why Business Men Fail.'

"I became interested in the article, and read it before moving from my chair. That night, in the quiet of my home, around the evening lamp, I took a delightful trip through the whole magazine. To my surprise I found much that I could use in my business — and I learned 'why some business men fail.' Now I make it my steady job to go through each issue thoroughly to get the ideas and plans which I can use in my business. And I honestly believe the reason prosperity came my way was because I took my trade paper into partnership, for I strike pay dirt frequently in its columns."

* * *

We know many successful business men who are eager and impatient for the day when the postman puts their favorite journal on their desks. You don't find these men consigning their trade journals to the waste basket—as leaders and executives in their special lines they always have time to learn something new about their business and its problems.

The growth of the trade paper in the past few years has been marvelous. It is coming more and more to be the successful business man's partner and associate. It supplies him with ideas and plans he needs and must have in these days of modern business — it keeps him posted in things he must know to be progressive.

E. C. Simmons, the St. Louis "Hardware Prince" who made "Keen Kutter" famous around the world, once said: "I spend an hour each day in quiet study of the day's problems, and my trade papers give me the angles on how the other man solved these problems, and I have found this hour the most valuable time of my business life."

Prosperity usually goes hand in hand with the man who has the ability to avail himself of the things which the other man has learned — who takes his trade paper into partnership.

HEPBURN CRANES

These easily manipulated, well-built cranes will prove a decided saving in the Power House. Hand cranes can be supplied for a moderate outlay. And while you are at it—What about pumps?
We make all kinds — Centrifugal — Steam Simplex and Duplex, and Power Pumps.

Cut Your Replacement Costs

Replacements of furnace linings, boiler settings, etc., is a costly operation nowadays. Why not avoid this trouble and expense by welding your Fire Brick into a solid one-piece structure with

STERNSON No. 30

the only Canadian Made High Temperature Cement that will give your furnace protection where it needs it most—at the joints. Sets harder than the bricks, withstands up to 3,000 deg. F. Try it out on a repair job.

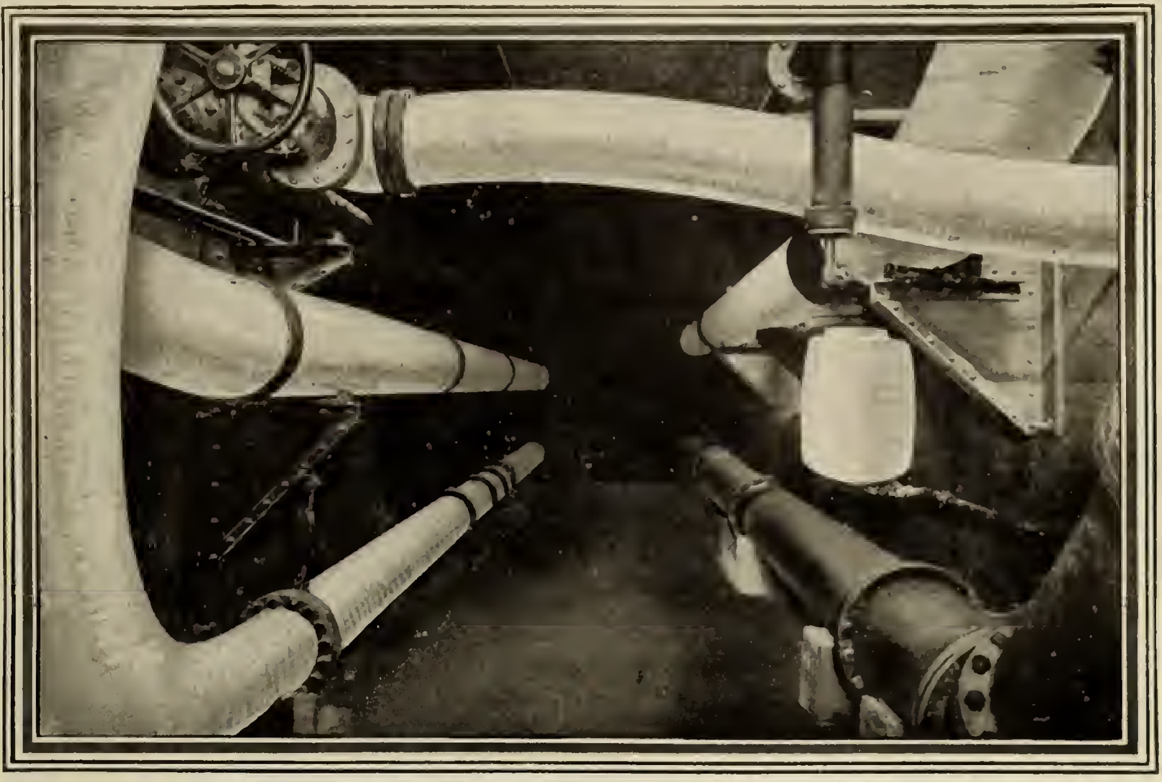
WORKS AT SHERBROOKE, QUE.



CRANE EQUIPMENT GIVES THE ASSURANCE OF UNFAILING SERVICE FROM THESE PIPE-LINES OF A LARGE FURNACE PLANT

WHEN DEPENDABLE STEAM PIPING COUNTS

Steam pipe-lines located in tunnels or basements or buried in the ground must give dependable service at all times. Crane valves, fittings and pipe bends for such installations are designed and produced to stand up under the most extreme conditions. Only selected materials are used in the manufacture of Crane equipment. Production operations are checked by rigid inspections, and searching factory tests guard uniform quality in the finished units. This careful factory practice gives exceptional endurance to Crane piping equipment.

A Jenkins Disc is Quickly Renewed
—without removing valve from line

A Jenkins Disc in a Jenkins Valve is the right combination—a tight-closing valve is assured. The disc has very long life, and, when necessary, it can be quickly renewed with the valve left in the line.

The compositions of the various Jenkins Discs are the result of constant study and 58 years' experience in disc manufacture. Each is exactly suited to the particular service for which it is intended.

Use the disc ONLY in the particular service for which it is recommended. If in doubt as to the kind of disc you need, let us know what work it is intended to do, and we will recommend the right one or prepare a special composition to suit your requirements.

A Jenkins Valve fitted with a Jenkins Disc—assurance of perfect valve performance.

The Euclid 105th Properties Saved 118 Tons of Coal with a 30% increase in load the first month with one Detroit Single Retort Underfeed Stoker

Mr. S. Cowan of the above company is authority for the following statement:

"We sell steam heat, hot water, electricity, and refrigeration, in the east end territory of Cleveland. We had been operating for 15 years with 3 . . . . . . Stokers and had been making approximately 96,000 units per month, until one Detroit Underfeed Stoker was installed in our plant as a test and we found that by the operation of this Detroit Underfeed Stoker that we saved one hundred eighteen tons of coal during our first month of operation. We produced 127,000 units of electricity during that period, an increase of 31,000 units over and above any previous month.

"We were so pleased with this showing that we contracted for the immediate installation of two additional Detroit Underfeed Stokers which are now in and giving entire satisfaction. We have no hesitancy in recommending the Detroit Stoker. We have tested and tried same in every manner possible and we find it absolutely satisfactory."

Experiences such as the above have caused concerns like the following to place repeat orders for Detroit Underfeeds:

Fifth Avenue Building, New York
J. K. Mosser Co., North Bend, and Newberry, Pa.
American Cotton Oil, St. Louis and Cincinnati
Harvey Hubbell, Bridgeport, Connecticut
National Home, D. V. S., Johnson City, Tenn.
Durant Motors, Flint, Michigan
God's Bible School, Cincinnati
Burroughs Adding Machine Co., Detroit, Mich.
Krippendorf-Dittmann Co., Cincinnati

If you want to effect *real* savings in your plant install a REAL Underfeed Stoker—the Detroit.

CANADIAN ALLIS-CHALMERS

— Steam Fire Pumps —

THE specifications under which our pumps are made have been adopted by the following associations:

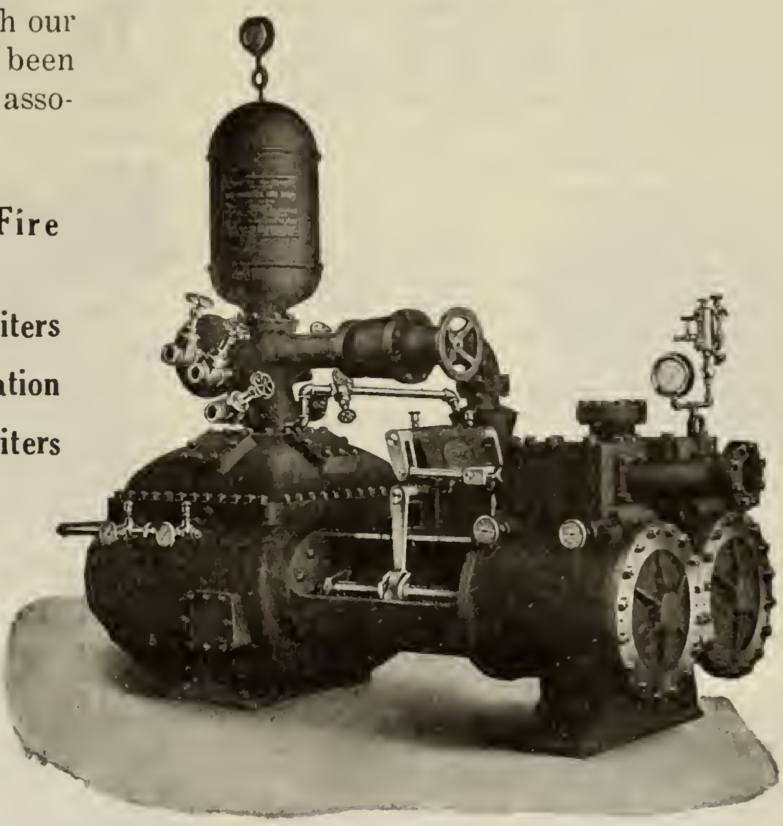
Associated Factory Mutual Fire Insurance Companies

National Board of Fire Underwriters

National Fire Protection Association

Canadian Board of Fire Underwriters

The Underwriter Fire Pump is a duplex steam pump, built in strict accordance with the specifications of the Associated Factory Mutual Insurance Companies, with the object of securing a fire pump superior in design, construction, and general detail to the ordinary trade pump.



"The National Standard"

1500-Gallon Underwriter Steam Pump

The Underwriter Steam Pumps Are Built In The Following Sizes:-

500—750—1000—1500 U.S.G.P.M.

AT A PRESSURE OF 100 POUNDS PER SQUARE INCH AT PUMP.

We Carry a Number of These Sizes in Stock and Can Make Prompt Shipment.

The Canadian Allis-Chalmers, Limited, were the first to develop this type of pump in Canada, and consequently having followed closely the various amendments to the specifications made by the Underwriters during the past twenty years, have a wider experience of the requirements than any other Canadian maker. In addition, we have designed special shop equipment and tools for the economical production of these pumps, ensuring absolute accuracy, interchangeability and the very highest efficiency in operation.

To Canadian Engineers—

The following letter from the Ingersoll Packing Company, of Ingersoll, Ont., is, we believe, the kind of advertising that appeals most strongly to intelligent, practical men.

> The Fisher Governor Co.,
> Marshalltown, Iowa.
>
> Gentlemen;
>
> We wish you would send us a new governor for our pickle pump to take the place of governor 8997 that we purchased from you 19 years ago.
>
> This governor has given us splendid satisfaction and we hope the new one will do the same.
>
> The size of the steam pipe connection is ½" and we use 50lbs. of air pressure on the diaphragm.
>
> Kindly send this to us as soon as possible.
>
> Yours truly,
> THE INGERSOLL PACKING COMPANY, Limited
> (signed) W. J. Peters
> Chief Engineer

The governor referred to is our Type 5 Diaphragm Governor. While the Ingersoll Packing Company used it to control a pickle pump, it is also in wide use on low pressure pumps where the controlling or discharge pressure is oil or other liquid, air or gas.

The construction of this governor is such that it is suitable for a number of other liquids.

The operation is very sensitive and positive and, as evidenced by this letter and hundreds of others in our files, the name "Fisher" means, long, satisfactory service.

The Fisher Governor Company

950 Fisher Avenue
Marshalltown, Iowa

Has No Weights or Levers To Tamper With

There is no danger of the Sarco Temperature Regulator being thrown out of calibration, for it has no weights, levers, or other parts to meddle with. Its calibration can be changed only by means of a key, which is removable and can be kept by the proper authority.

A special safety device prevents over-temperature from straining the instrument.

Only enough steam is supplied for the job, by its gentle throttling action—instead of supplying a large quantity and then shutting it off entirely. No other self-contained instrument has such a fine control as the

SARCO
Temperature Regulator

Its powerful hydraulic pressure enables the Sarco to cut through any scale that may get into it, thus preventing the valve from becoming stopped up.

The Sarco will operate in locations where a regulator of the volatile liquid type would not operate; due to the temperature of the room being almost as high as the temperature it is desired to control.

Other equally important advantages of the Sarco are explained in our interesting Booklet J-78. Write for a copy and information about our free trial offer.

De Laval Steam Turbine Co.

TURBINE EQUIPMENT CO., LTD.
73 King St., West, Toronto

THE E. LAURIE COMPANY
243 Bleury St., Montreal, Que.

Products

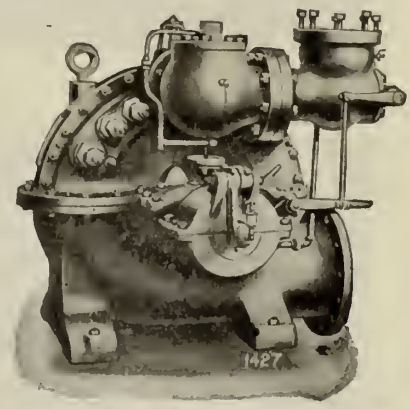
STEAM TURBINES; CENTRIFUGAL PUMPS; BLOWERS and COMPRESSORS; SPEED-REDUCING GEARS.

Also manufacturers of Special Centrifugal Machinery.

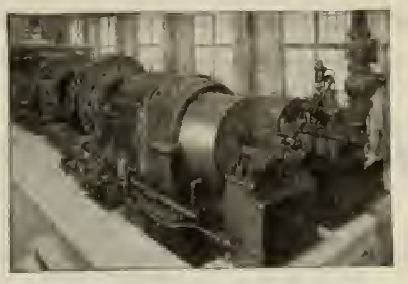
Steam Turbines

In the production of steam turbines, we offer the combined advantages of standardized design and quantity production, combined with a sufficient selection of types to suit each user's requirements.

De Laval turbines are built for all steam conditions, such as high pressure, condensing and non-condensing, back pressure, bleeder and mixed flow service. They are also adapted to driving machines at all speeds, either directly connected or through the De Laval double helical speed-reducing gear.



De Laval Velocity Stage Turbine
Throttle valve controlled by speed governor and shut-off valve by emergency trip.

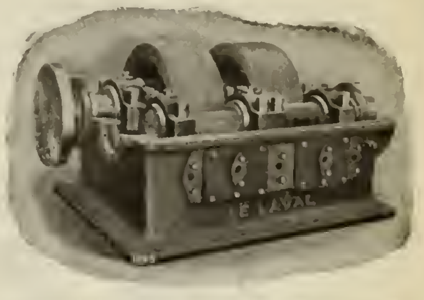


De Laval Geared Turbine Driving Direct Current Generator, 3750 Kw.

The De Laval velocity stage turbine has been designed to operate on high pressure, high temperature steam. The steam chest and governor valve, which are the only parts with which the steam comes in contact, are made of steel and so located that heat is not readily conducted to the bearings. De Laval velocity stage turbines are made in all sizes up to 1,200 h.p. The hand controlled valves for cutting out nozzles permit of high efficiency under varying loads and steam conditions.

Centrifugal Pumps

De Laval centrifugal pumps are characterized by conservative speeds, high class materials, construction on a limit-gage interchangeable basis, guaranteed efficiency and capacity, and a comprehensive system of testing by which the fulfillment of these guarantees is demonstrated. The casing is split horizontally, the suction and discharge connections and the bearing supports being included in the lower part. The De Laval labyrinth wearing ring assists materially in maintaining the original efficiency, as it does not require small clearance in order to prevent excessive leakage. Finished repair parts are supplied, made to accurate dimensions so that they can be put in a pump without requiring to be fitted.



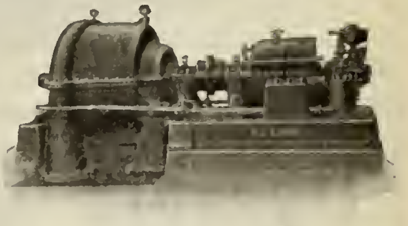
De Laval Double Helical Speed-reducing Gear.

Speed-reducing Gears

De Laval speed-reducing gears are of the double helical type and the result of over 25 years' experience in building reduction gears for steam turbine service. The cutting methods employed are such that the correct pitch, angle and tooth contour are produced, and quiet running and long life are secured.

Centrifugal Blowers and Compressors

De Laval centrifugal blowers and compressors are built for all pressures up to 120 lb. per sq. in. With electric motor driven compressors for high pressures, efficiency and economy are improved by the use of speed increasing gears.

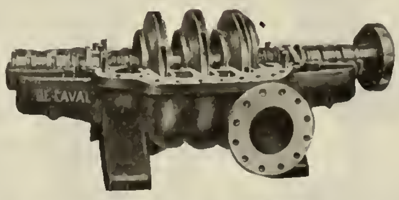


De Laval Turbine Driven Multi-stage Compressor.
16,000 cu. ft. of air against 8½-lb. gage pressure.

De Laval Construction

All De Laval apparatus is built on a limit gage, interchangeable basis. The performance of every machine is guaranteed, both as to capacity and efficiency, and a complete test is carried out before shipment. Engineering suggestions and special publications will be sent on receipt of letter describing the conditions.

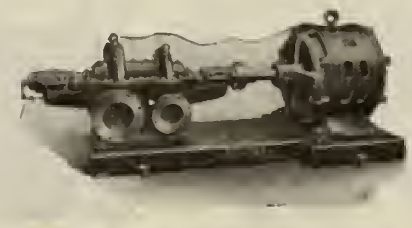
De Laval pressure stage turbines, built in capacities up to 15,000 h.p., give the highest obtainable efficiencies. Turbines of this type connected to De Laval double helical gears and driving standard direct current generators, excel in economy large turbo alternators when transformer and converter losses are included. Large geared turbine driven centrifugal pumps rival triple expansion pumping engines in duty.



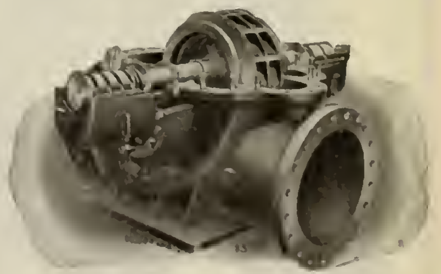
Multistage Pump with Casing Cover Removed.

One of Three De Laval Geared Turbine Driven Centrifugal Pumps for the City of Chicago.
60,000,000 gal. per day each against 150-ft. head.

De Laval Velocity Stage Turbine Driving Centrifugal Pump.



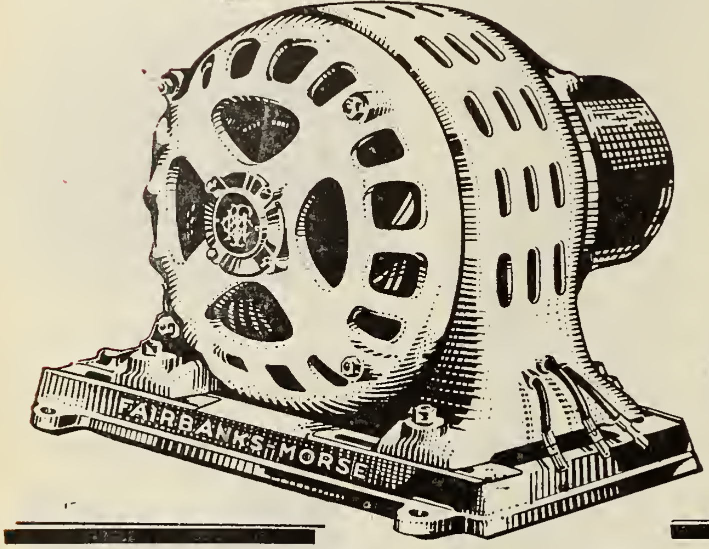
Two Stage Series Pump, Motor Driven.



Single Stage Pump with Casing Cover Removed.

Why

Fairbanks Morse
Ball Bearing
MOTORS



1. They reduce friction—therefore save current.
2. They require lubrication but once a year—therefore save lubricant and maintenance charges.
3. The one-piece rotor winding means no loose joints, flashing or sparking.
4. They outlast any sleeve-type bearing motor.

A full explanation of these and other points of superiority is contained in our booklets. Prudent executives will ask our nearest branch for them.

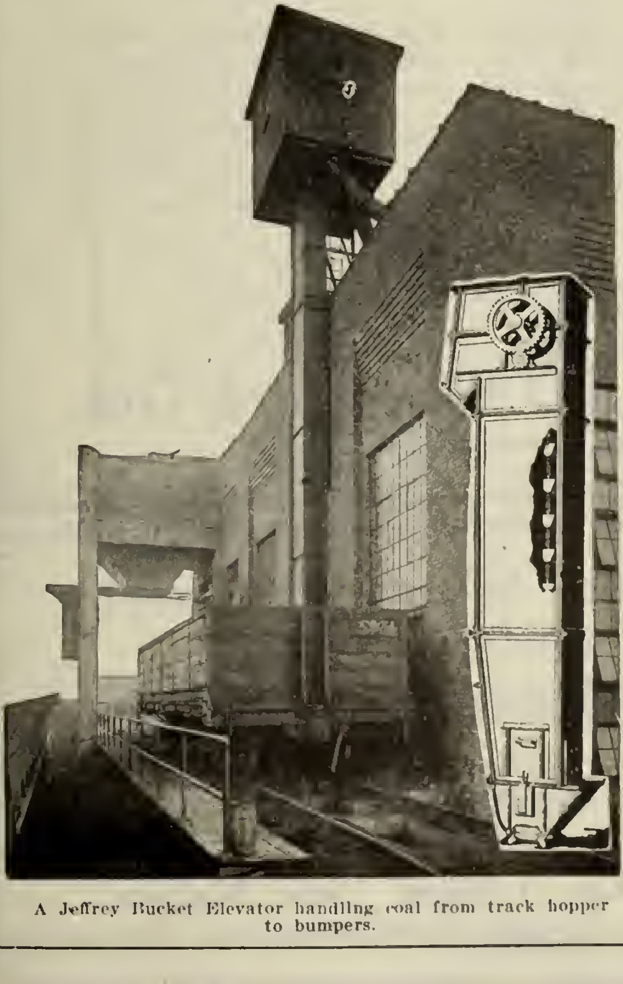
Jeffrey Pivoted Bucket Carrier for handling coal and ashes in large size plants. *Catalog No. 210—fully illustrates and describes it.*

V-Bucket Elevator-Conveyer. May be used either as a rectangular or run-a-round conveyer or as a combined elevator and conveyer.



A Jeffrey Bucket Elevator handling coal from track hopper to bumpers.

For Over Forty Years

Jeffrey Engineers have co-operated with the men responsible for results in power plants:

This has been productive of successful coal and ashes handling equipments, which have been a deciding factor in producing a constant supply of power at the lowest possible cost.

To meet the imperative demands of industry today will mean in many plants, new methods, faster and more dependable material handling equipments, Jeffrey experts are ready to help you select the right equipment to meet the emergency.

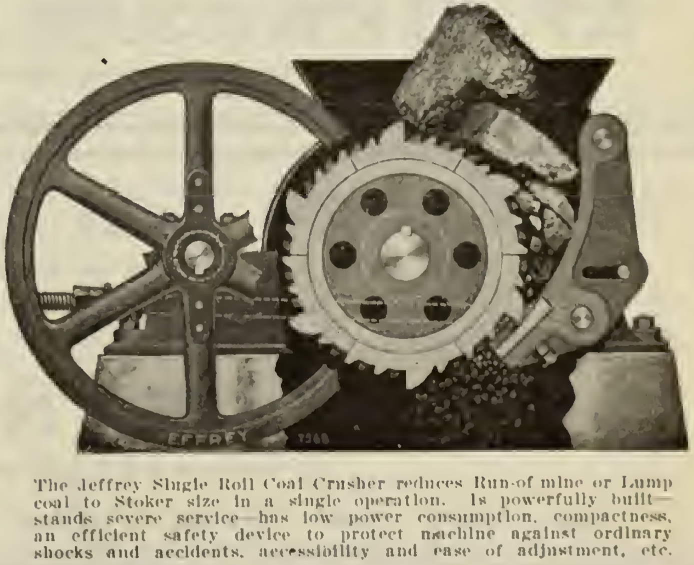
Jeffrey Coal and Ashes Handling Equipments include: Track Hoppers, Reciprocating Plate and Apron Feeders; Coal Crushers; Conveyors; Bucket Elevators; Weigh Hoppers, Skip Hoists; Portable Bucket Loaders and Belt Conveyors; Industrial Locomotives, etc.

The Jeffrey Manufacturing Company

Canadian Branch and Warerooms: Montreal

JEFFREY

MATERIAL HANDLING MACHINERY



The Jeffrey Single Roll Coal Crusher reduces Run-of mine or Lump coal to Stoker size in a single operation. Is powerfully built—stands severe service—has low power consumption, compactness, an efficient safety device to protect machine against ordinary shocks and accidents, accessibility and ease of adjustment, etc.

"BURN ALL"

Reduce Your Coal Bills

Use Sternson Service

Boiler Brand—
Silicate of Soda

It is the simplest and most inexpensive and effective boiler feed-water treatment on the market. It not only removes scale, but it prevents new scale from forming. Less scale in the boiler, less fuel required!

Sternson No. 30—
High Temperature Cement

It ensures absolutely tight, enduring joints in your furnace. It makes the weak parts strong and withstands 3,000 deg. F. This fuel conserver is shipped to you ready to use.

Sternson No. 40—
Plastic Fire Brick

Monolith—a plastic ceramic mixture, which gives you a jointless, gas-tight furnace or fire-box lining—and a fuel saver which is lower in cost to apply than the old method of fire brick and mortar.

You require less fuel but get adequate heat from the moment you commence to use STERNSON SERVICE.

G. F. STERNE & SONS, LTD., Brantford, Ont.
Chemical Manufacturers, Consulting Chemical Engineers.

Why Individual Boiler Feed Water Treatment

Because the Condition of Each Individual Boiler Differs

We have demonstrated it to be the most successful method of freeing boilers of scale and stopping the further formation of scale-forming deposits or incrustations. Corrosion or pitting stopped at once by our scientific process which accomplishes the results desired.

"CLEAN ALL"

Indicates in a few words what the process does.

STEEL CONCRETE SKYSCRAPERS IN JAPAN STOOD UP

American Earthquake Proof Construction Withstood Recent Severe Shocks.

MAY AFFECT FAVORABLY THIS TYPE OF BUILDING

Import Shipments to Go Via Kobe for Some Time, Trade Commissioner Cables.

Washington Bureau, New York Commercial.

Washington, Sept. 13.—American steel concrete buildings in Tokyo and Yokohama withstood the earthquake shock and are in good condition, according to a cable from Assistant Trade Commissioner Howard at Kobe. Officials of the Department of Commerce expressed gratification over the first practical demonstration of the effectiveness of the new so-called earthquake-proof factories and office buildings which have been constructed within the past three years. There are about six of these buildings in Tokyo. The fact that this construction has proven earthquake-proof is likely to influence favorably the adoption of this type of construction in future.

CONCRETE
Proves its Permanence

Concrete, adopted in Japan as an earthquake-proof building material, has met and successfully weathered the severest of all possible tests — the biggest earthquake of modern times.

While buildings of less rugged construction and inferior durability crumbled under the repeated shocks or were licked up by the ensuing flames, those of steel and concrete remained unscathed. Neither quake nor fire could hurt them.

They stand to-day, in a sea of ruin, monuments to the indestructibility of Concrete construction, justifying the foresight of the men who built them.

A Marvel of SIMPLICITY

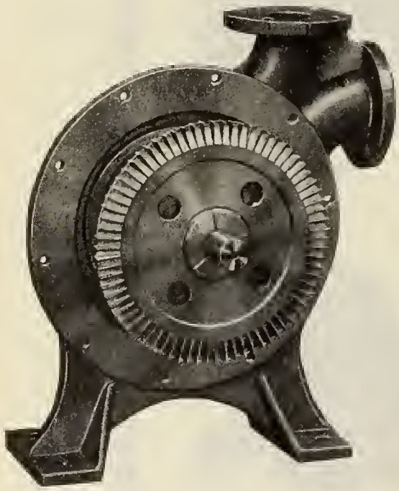
Westco Pumps

SPECIALLY ADAPTED FOR

Fire Protection, Oil Burner Installations, Boiler Feed Transfer and Booster Work

One Moving Part—SIMPLICITY

The simplicity of the Direct-Driven Valveless Westco Pump with a remarkable pressure supersedes the reciprocating pump in a large field of application. For fire protection it pumps 90 gallons a minute against 90 lbs. pressure; for driving oil burners Westco Pumps are giving satisfaction on 24 hours' continuous duty; and for boiler feed and booster work they give pressure beyond the ability of the smaller centrifugal pump with simplicity of direct motor drive.



Consult us—our staff of technical and practical experts will gladly assist in solving your pumping problems.

Westco-Chippewa Steady Stream Pump
For Deep Well Water Supply.

WESTCO MFG. CO. LTD., 220 King St. W., Toronto

Makes Short Work of Boiler Scale

In hundreds of plants BOICO has been adopted as the one sure clean-boiler insurance. The speed with which it removes the most stubborn scale formations is surprising. Hurts nothing but boiler scale. It's economical, too.

TRY IT FREE—let us send you a sample to convince you. Write us to-day—you've nothing to lose.

TURN OUT!

THE success of last year's Power Exposition showed conclusively that engineers, manufacturers and others interested in power plant equipment keenly appreciate the value of this show.

It offers an opportunity to gain a great deal of information in a short time and to establish personal contact with the various people who supply power equipment, and with engineers of national reputation.

In addition to the impressive array of primary apparatus, there will be exhibits of stokers, pulverized-fuel and coal handling equipment, firebrick, refractories and refractory cements, water purifiers, feed-water heaters, economizers, superheaters, blowers, valves, piping, pipe covering, steam separators, pumps, etc.

CONTROL APPARATUS will occupy considerable space and a special TRANSMISSION SECTION is being prepared.

The big national engineering societies will be there in full force, seeking new ideas and information. Many of the members, ready to buy power equipment, will doubtless follow precedent and avail themselves of this convenient opportunity to make their selections.

Don't Miss This Important Exposition!

Dec. 3rd - 8th, 1923

Grand Central Palace, New York

To Manufacturers!

If you have something of positive merit and capable of comparison which is used either in producing, transmitting or using power, or some mechanical equipment, or supply or materials used by the mechanical industry we welcome you as an exhibitor. Every application is subject to Exhibits Committee approval and no article can be exhibited unless it possess real merit.

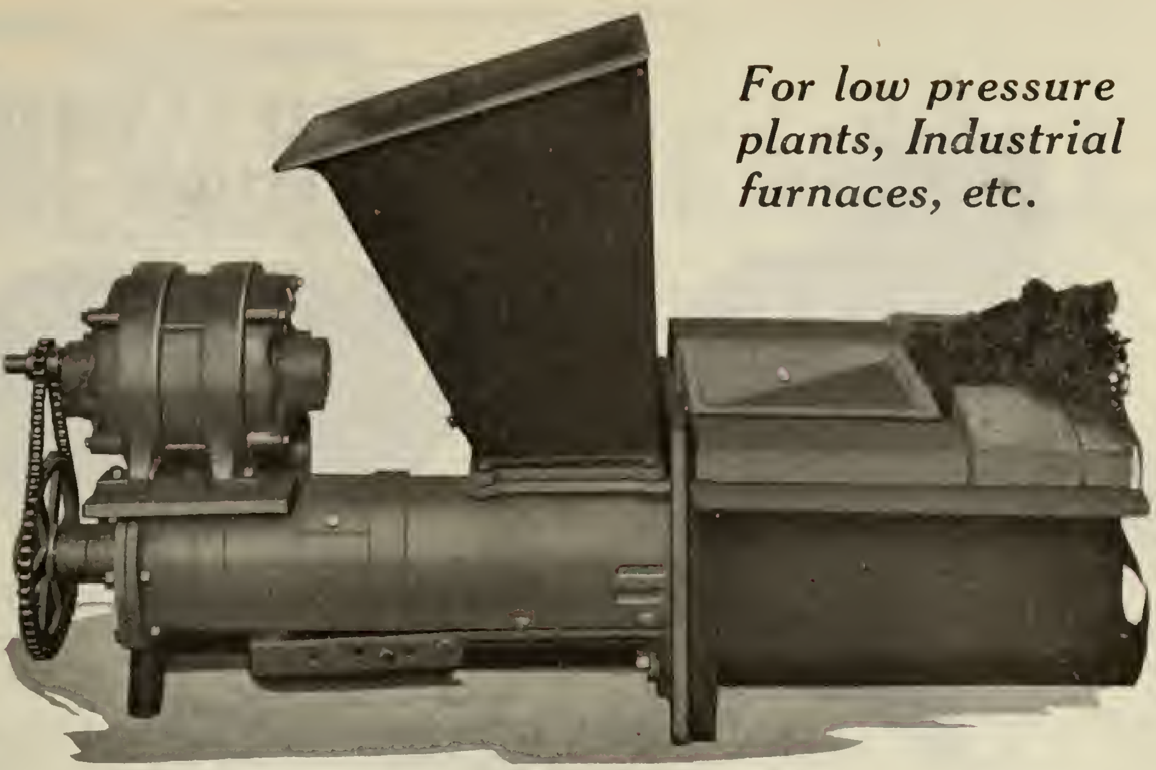
YOUNG PUMP COMPANY OF CANADA

96 Mary St. - Hamilton, Ont.

Manufacturers of the Young Centrifugal Vacuum and Boiler Feed Outfit



For low pressure plants, Industrial furnaces, etc.

A Perfect Electric Drive for Jones Stokers

THIS simple and effective electric drive greatly broadens the range of application of the Jones Stoker. It solves the drive problem for low pressure heating plants or industrial furnace installations where steam for driving the stoker is not available.

The illustration shows the simplicity of the equipment—simplicity in keeping with the unapproached simplicity of the Jones Stoker. A small motor drives a large screw-threaded shaft, causing a nut to move as the shaft is rotated. The coal ram is secured to this nut and is moved inward or outward depending on the direction of rotation of the motor.

An automatic contactor, usually driven from the fan shaft, causes the motor to run in one direction until the charge of coal is fed and then the contactor reverses the motor and the ram is withdrawn.

The timing of the ram, and therefore the rate of firing, is automatically regulated, but provision is also made for hand regulation.

The device uses less than 1/3 H.P. per hour, making the power cost practically negligible. Ask for complete details of this and other improvements in Jones, Murphy and Riley Stokers—a make and type for every service.

Above: Jones "Standard" Stoker with new electric drive, omitting housing for motor and drive. Below: Automatic Contactor with provision for manual and automatic regulation.

Just a Hammer to Apply It

For Every Size and Kind of Belt

BOILER CHEMICALS

Made in Canada for You

Do it Now

Not a hit-and-miss ready-made compound, but made for you on scientific principles.

Send us ½ gallon sample of the water used in your boiler, together with a description of your boiler plant, for analysis, and be convinced.

THE BIRD-ARCHER CO.

Office: McGill Bldg., Montreal **Factory: Cobourg**

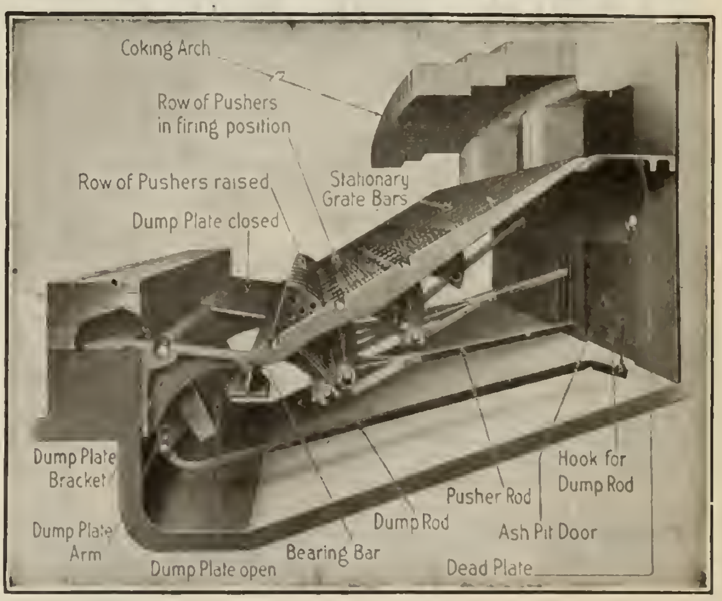
You Need the National hand fired Stoker

The National Hand Fired Stoker consists of a system of downward sloping grate bars, fuel pushers, dump plates, boiler front, bridge wall and ignition arch. In firing all that it is necessary to do is to dump the fuel on the upper end of the grate and when this is coked it is moved a stage further down by means of pusher rods operated from the front of the furnace, and the fresh charge of fuel may be dumped in.

No need to spread the fuel—any "green" hand can thus do the firing. The successive pusher rods keep the fuel marching downward, ensuring perfect and smokeless combustion, until the lowest or dump grates are reached. The draft is evenly distributed throughout the fire bed and excellent results can be secured with waste and low grade fuels.

You get all the advantages on a smaller scale, and without the great cost, of the large mechanical stokers.

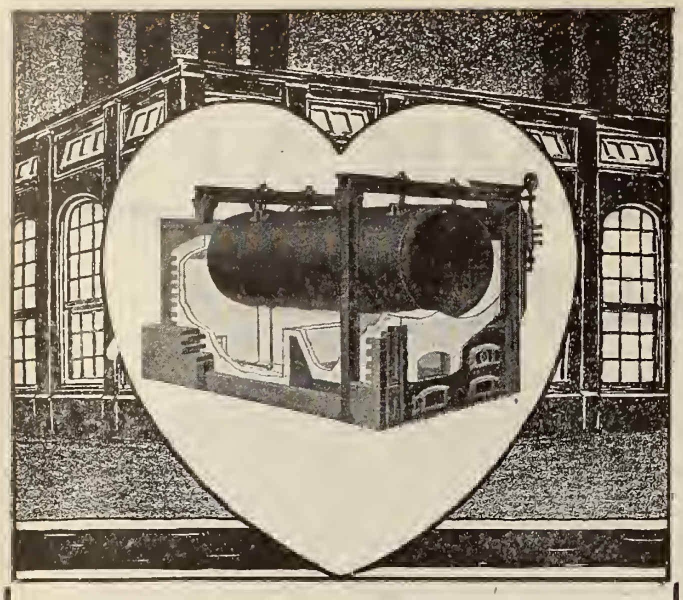
Booklet mailed on request.



Engineering and Machine Works of Canada, Limited

ST. CATHARINES, ONT.

Eastern Sales Offices: **HALL MACHINERY CO., Sherbrooke, Quebec, and Birks Bldg., Montreal**



The Heart of Your Plant Is the Boiler Fire Box

Insure long and efficient service of this vital organ by using only monolithic walls, arches and baffles. Eliminate separate bricks, blocks, tile and mortar joints. These are the weak points—the trouble makers.

BETSON'S

REG. U.S. TRADE MARK PAT. OFF.

PLASTIC FIRE BRICK

is the pioneer material for this purpose. Well-known Chief Engineers use and recommend it. Many Power Plants have used it continuously for 10 and 20 years. Replies to a recent questionnaire show that it has reduced the item of lining and baffle repairs 50 per cent.

Ask us for a list of BETSON users. Ask them. Investigate our claims. There'll be no more bricks to drop out and no mortar joints to open up once you use BETSON'S PLASTIC FIRE BRICK.

Shipped in substantial wooden barrels from warehouses in principal cities, either mixed ready for use or dry ready to be mixed with water. The cost is no more one way than the other.

Get the vital facts about Power Plant Efficiency and Economy. Write to-day for our FREE Booklet.

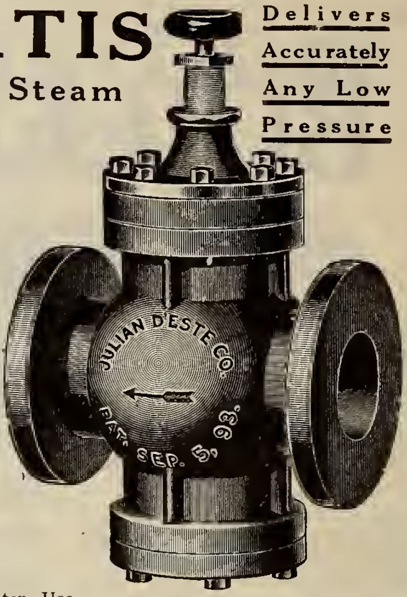
CURTIS

Improved Steam Pressure Regulator

Delivers Accurately Any Low Pressure

A compact, self-contained Regulator suitable for any boiler pressure. It delivers accurately and uniformly any lower pressure from one to within a few pounds of the initial pressure.

It has no levers, weights or projections; no glands or packing; no drip or leak of steam or water. Use it for efficient service on steam-heating apparatus, slashers, jacket kettles, air or water pumps, pulp mills, etc.



The Improved Steam Pressure Regulator is a lock valve, very simple and sensitive. Send for descriptive pamphlet.

JULIAN D'ESTE COMPANY

Main Office: 26 Canal St., Boston, 14, Mass.

Tycos and Condensers

The application of *Tycos* Bi-Record Recording Thermometers on condensers gives accurate records of both in-coming and out-going temperatures. A study of these records of rise and drops between two points enables operators to maintain condenser efficiency.

For every temperature need in the power house there is a *Tycos* Temperature Instrument, Indicating—Recording and Controlling that will completely meet that need.

Send to-day for our reference book on power plant temperature instruments.

Size C for 26,000 square feet radiation requiring only 2 H P. Motor at 1800 R.P.M. when delivering from a Vacuum of 10 inches of Mercury against a boiler pressure of 10 pounds.

THE Pump consists of two independent turbine units, an air pump and a water pump combined in one casing, with the impeller of each mounted on the same shaft.

One unit continuously exhausts air and vapors from the heating system, and the other removes the condensation as it accumulates and forces it directly into the boiler, or up to the hot well.

The boiler pressure is against the water only. The air and vapor, representing approximately four-fifths of the volume handled, are delivered to the atmosphere without back pressure. The saving in horse-power amounts to over 50 per cent.

No oil from the pump can get into the boiler, as the pump has no internal lubrication; and no air separating device or water leg is required, as the pump discharges direct to the boiler.

HIGH GRADE POWER PLANT AND PUMPING EQUIPMENT

Protecting the Steel Industry

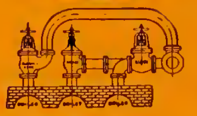
Safety to life and property and the elimination of preventable shut downs are of vital importance. The engineers of the big steel companies have left nothing to chance. The serious hazard due to sudden reversal of steam flow from a boiler room header into a damaged boiler or liability of a disastrous explosion following a break in a steam main has been removed in their plants by the installation of

"4300"

Golden-Anderson

Patented Automatic Double-Cushioned Triple-Acting and Non-Return Valves

1. Automatically cut out a boiler the instant that a tube ruptures or other internal break occurs.
2. Automatically cut off the steam flow from every boiler the instant that a steam pipe bursts.
3. Automatically equalize the pressure between all boilers.
4. Automatically cut in a boiler, making accidents due to inaccurate steam gauge impossible.
5. Positively prevent back flow of steam into a cold boiler.
6. Can be closed by hand like ordinary stop valve, and arranged with "combination feature" to open valve like regular gate or globe valve.
7. Can be tested in service from the boiler room floor.
8. Double Corliss Dash Pot that cushions in opening and closing.
9. Cannot pound, spin, stick or chatter.



Double Extra Heavy Valves

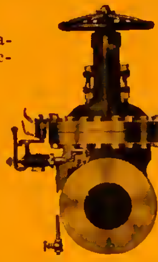
"CUSHIONING"

is of most vital importance in triple acting and non-return valves. Steam is no respecter of makers. Insist on "Double Corliss" Dash Pot Cushioned Valves.

GOLDEN-ANDERSON

Pat. Cushioned Combined Throttle and Automatic Engine Stop Valves.

1. Operate 3 ways: Automatically, by Hand or by Electric Switch.
2. Prevent fly-wheel Explosions.
3. "Double Corliss" Cushioned— No Pounding or Sticking.
4. Contains No Tight Fitting Parts.
5. Furnished in Angle and Globe Patterns for High or Low Pressures.
6. "Always Ready for Service."



GOLDEN-ANDERSON

Pat. Automatic Cushioned Controlling Float Valve.

1. Automatically maintains uniform level in heaters, tanks, etc.
2. Air and water cushioned.
3. No metal-to-metal seats.
4. No waste of water.
5. No water hammer or shock.
6. Angle or Globe patterns to 30 in.

GOLDEN ANDERSON

Pat. Automatic Cushioned Water Float Valves.

1. Automatically Maintain Uniform Water Levels in Tanks, Standpipes, etc.
2. Instantly Adjusted to Operate Quickly or Slowly.
3. Floats Swivel to any Angle — Most Satisfactory Float Valves Known.
4. No Metal-to-Metal Seats — No Water Hammer or Shock.
5. Cushioned by Water and Air.

GOLDEN-ANDERSON

Patent Automatic High and Low Pressure Steam Traps.

1. The first new departure in steam trap design, in years.
2. 50 to 100% greater capacity than other traps of similar size.
3. Full area through discharge valve.
4. Extra Heavy Throughout — Very Durable — Will last a lifetime — and Always Works.
5. Furnished Semi-Steel and Cast Steel for Superheat.

GOLDEN-ANDERSON

Pat. Cushioned Water Relief Valves.

1. Automatically relieve excess pressure.
2. Prevent stress, strain and bursting of mains.
3. Correct mechanical construction.
4. Perfect air and water, cushioning.
5. No metal-to-metal seats. No hammering or shocks.
6. Angle and globe pattern. Sizes 3 to 30 in.

GOLDEN-ANDERSON

Pat. Automatic Double Cushioned Check Valves.

1. Especially adapted for Water Service.
2. For High or Low Pressure.
3. Thoroughly Cushioned. No chattering, Hammering, or Sticking.
4. Globe or Angle Patterns up to 30 in.
5. Especially adapted for hydraulic elevator service.

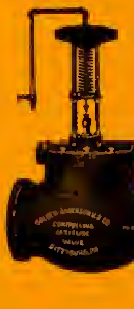
GOLDEN-ANDERSON

Pat. Automatic Cushioned Steam Pressure Reducing Valves.

1. Maintain a constant reduced pressure.
2. Thoroughly cushioned.
3. No hammering, chattering or sticking.
4. No auxiliary valves or small by-passes to clog up.
5. No wire drawing.
6. Only one adjustment from the outside.
7. Double extra heavy throughout — practically indestructible.

GOLDEN-ANDERSON

Pat. Cushioned Automatic Controlling Altitude Valves.



1. Automatically Maintain Uniform Water Levels in Tanks, Standpipes, Reservoirs, etc.
2. For High or Low Pressure. Always Dependable.
3. No Floats or Fixtures used.
4. No Water Hammer or Shocks.
5. Sizes up to 30 in.

GOLDEN-ANDERSON

Pat. Automatic Cushioned Water Pressure Regulating Valves.

1. Maintain a constant reduced pressure regardless of fluctuations on high pressure side.
2. Perfectly Cushioned by water and air. No metal-to-metal seats.
3. The best valve made for maintaining a constant low pressure where consumption is continuous.
4. Operates quickly or slowly as required—No attention necessary.
5. Positively no hammering or sticking. Sizes to 24 in.

You can carry your heaviest peak load with the cheapest fuel available if you equip your boilers with

REGISTERED
COPPUS
U.S. PAT. OFFICE

TURBO-BLOWERS

If You Fire by Hand—

A COPPUS Type "C" Turbo Blower placed in the boiler wall will result in a marked saving in fuel and insure higher steaming capacity and steady pressure. It occupies no floor space and is designed for continuous operation under boiler room conditions. Can be controlled automatically or by hand.

Type C Undergrate Blower

Turbine Driven VANO Blower

For Mechanical Stokers and Induced Draft—

we have developed the COPPUS VANO BLOWER with either turbine or motor drive.

COPPUS VANO BLOWER
"IT'S ALL IN THE VANES"

The VANO is unquestionably the most efficient blower yet built. It combines the advantages of the centrifugal and propeller blower—is more efficient than either and admirably adapted for direct motor or turbine drive. Be sure to investigate.

Electric Driven VANO Blower

The Efficient Way To Pump Feed Water

The COPPUS Turbo Feed Pump was specially developed to bring the high efficiency and even feed pressure and other advantages, resulting from the use of centrifugal feed pumps, to the small and medium size plant.

Type TB Coppus Centrifugal Boiler Feed Pumps, multi-stage — the latest development in the feed pump design. Adapted to service with the highest modern boiler pressures.

Write us for full set of Coppus Bulletins. Consult us regarding your special requirements.

Type CCC Coppus Centrifugal Turbo Boiler Feed Pump, single stage. Insures smooth, steady feeding for moderate boiler pressure.

HIGH GRADE POWER PLANT EQUIPMENT

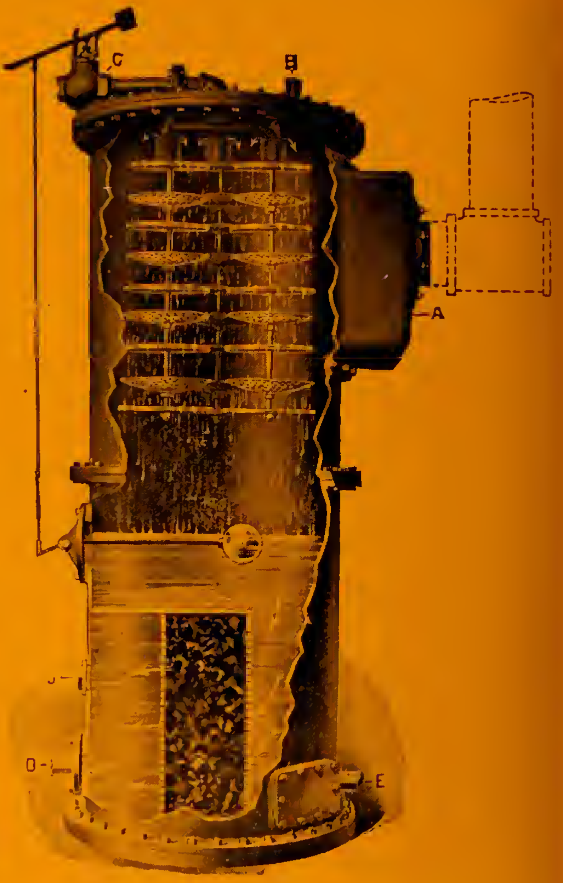
"SIMS"

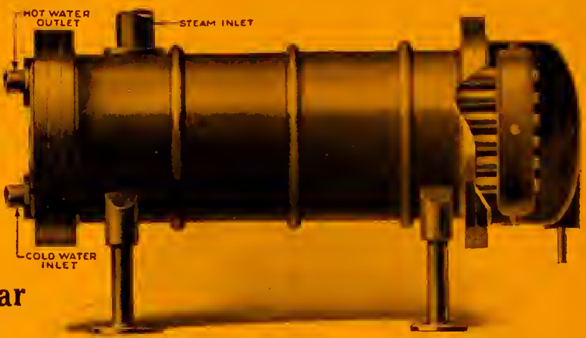
Hot Water Heaters and Generators

SIMS Heaters are designed and constructed to give service. Economy in operation is one of the outstanding features.

Tubes can be easily cleaned, due to the construction.

Straight tubes are expanded into a floating header which takes care of the necessary expansion and contraction.





"Sims" Closed Tubular Feed Water Heater

"Sims" Hot Water Generators

"Sims" Open Feed Water Heater

With the "Sims" Closed Tubular Feed Water Heater the temperature of feed water can be raised within a few degrees of boiling point with exhaust steam. All heaters are made up with straight, seamless drawn brass tubes 1½" O.D., subject to factory test of 1,000 lbs. per sq. in. The tube structure is tested at 250 lbs. hydrostatic pressure.

"Sims" Hot Water Generators and Convertors are designed for heating water for all kinds of service. They are efficient and economical. Tube covers are easily removed, exposing all the tubes so that they can be scraped and kept in good order as when new.

"Sims" Steam Storage Heaters

"Sims" Open Feed Water Heaters are round, the best for withstanding internal pressure; they are constructed of cast iron, the only material which is not subject to corrosion. The design is very simple, every part is easily accessible.

Practical Uses For B.H. Clean E-Z Storage Heaters

These heaters are adapted for use in any plant or building requiring hot water, with either high or low pressure steam. Installations are in service in factories, office buildings, Y. W. and Y. M. C. A. buildings, hotels, apartment houses, steam laundries, etc.

CANADA STOKER

CANADA STOKERS

Effect a Remarkable Saving in Fuel

Canada Stokers applied to 150 h.p. H.R.T. boilers as shown above have made it possible for four boilers to produce same amount of steam formerly produced by six boilers when hand fired. Only two men are now required instead of four. These stokers, although in continuous service for four years, have cost nothing for repairs.

The owner of another plant says: "Shortly after Canada Stokers were installed our load demand was increased about 15 per cent., but, despite this, we have saved fully 10 per cent. in coal. Furthermore, our efficiency, evaporation and capacity have been greatly increased."

CHAIN GRATES

We have placed on the market a narrow link, non-sifting, British Standard, high grade traveling grate adaptable to natural or forced draft.

Being continuously self-feeding and self-cleaning, it does not require dump plates, there being no large masses of solidified clinker to frequently dispose of, as is the case with several other types of stokers.

This stoker is entirely automatic in all its functions and is driven by a seven-speed fully enclosed gear box, running in oil.

We also furnish pumping machinery, portable flow meters, boiler feed water regulators and pump governors, feed water heaters, crushing and pulverizing machinery, and flat suspended arches for every type of furnace.

POWER HOUSE

ARTHUR MURPHY
Editor

CAMPBELL BRADSHAW, Managing Editor

N. C. SHATFORD
News Editor

Why is Money More Sacred?

EVERYONE is familiar with sales contests among road men, dealers and branches. Their regularly growing popularity is ample proof that they produce results—that they pay—and this "paying" is what we are interested in.

Rarely does it occur to an executive that a profitable contest can be staged right in his own power plant. He is alert to the value of prizes for salesmen whose expense accounts are audited with a sharp pencil, forgetting that firemen count money with scoop shovels which comes out of the same bank account.

Whether we have one boiler and one fireman or five boilers and eight-hour shifts, is immaterial. Set one lone man a mark to shoot at, or turn a number of them loose to beat each other; so long as it is a fair contest with a sound motive the executive is bound to get results. And the outcome—no matter who wins, is sure to be in his favor and to pay him in cash.

The more difficult the conditions are in the boiler room, the greater the need of directing attention to them. Men cannot, will not, and do not work well under continual handicaps and annoyances any more than money will. Yet, as a rule, money and its preferences are considered much more sacred. Be as selfish as we desire, we are bound to emerge at the identical point in every case where we are forced to realize that both factors, men and cash, are vitally necessary to have present in good order, willing and in good humor. Cashing in on either through proper use and adaptation of the other improves dividends.

All of which is but another sidelight upon the unpleasant truth that there is too great a tendency to neglect the boiler room and the kind of work done in it because it is dirty and uncomfortable—therefore we usually get the sort of returns to which poor equipment and our conduct has entitled us.

* * * *

Poor Stoker Operation

IMPROPER stoker operation is a very common cause of poor boiler results in Canada. A hand fireman often, unfortunately, makes a very poor stoker operator. He is hard to convert, and still believes there is no tool equal to the hook and slice bar—and he bravely attempts to live up to his opinion. This does give temporary relief, but it has serious after-effects, and often ruins the work of the best stokers. Overfeeding the coal is also a very prolific breeder of stoker trouble.

When the complaint regarding stoker operation is what might be termed general, a good safe rule is to shut down a stoker, go over every part of it in detail, tighten loose bolts, and do everything possible to make it as nearly new as possible. Then the blowers, flues and tubes should be inspected and everything put in first-class order before the stoker is started. This will naturally give good results, and will prove conclusively to the engineer, that by keeping everything up to concert pitch, satisfactory boiler operation will result with far greater economy than ever possible before.

Burning Oil Fuel

IN THE everyday operation of oil fuel burning plants there are certain axiomatic rules which must be adhered to at all times in order that the safety of the plant and its operators may be assured. The term "casualties" is perhaps the most appropriate to apply to accidents which might result directly from careless handling and burning of oil fuel.

Explosion may be caused by neglected leakage, accumulation of oil vapors in unfrequented places, and flarebacks within the furnace; ignition in the first two cases being caused by contact with a naked flame, flash or spark of some nature. Fire may be considered to be the result of explosion in practically every case.

Flareback as a cause of explosion is probably the most general operating casualty to guard against. It may or may not be serious, depending entirely on the extent of the explosion within the furnace, and the amount of explosive oil vapor present in the furnace. In general, it may be said to occur when lighting up, due to the accumulation of oil vapors within the combustion chamber occasioned by leakage from the burner tip.

The most general rules for safe operation may be outlined as follows:

Do not allow leakage of oil to continue at any point whatsoever in the system.

Do not allow spilled or leaked oil to accumulate; wipe up immediately.

Do not allow oil vapor to accumulate in a furnace. It is well to blow the latter through with steam or air before lighting off a burner.

Do not stand directly in front of a burner when lighting off. It is best to use a torch at least four feet long, and to stand at one side of the burner so that in case of flareback the chances of personal injury will be as slight as possible.

Old Things in New Dress

OF COURSE you've noticed the new "masthead" on the cover this week. All of us like change—even "small change." And so every little while there is something new in Power House—we take out something old, or move things around a bit, just to add to the interest and freshen up the pages.

From month to month there will appear new things—things that will interest you, please you, help you in solving your every day problems. Then, too, old things will dress up in new dress, or will take a fresh twist or turn. You're going to like all this for there's a heap of satisfaction in watching for the unexpected. And you may look for the unexpected every time the paper arrives.

To keep up with the progress being made to-day in the power plant field in Canada there is just one thing to do. As soon as the postman hands you your copy, pull it out of its wrapper, and turn every page from cover to cover. Not to do this will be to miss something you'll be sorry you missed.

Effecting Big Savings Through Control of CO_2

By ROBERT JUNE, A.S.M.E.[*]

In This Article the Author Emphasizes the Fact That Flue Gas Analysis Will Not Improve Boiler Room Efficiency, in and of Itself, Its Purpose Merely Being to Ascertain a Basis for Intelligent Action

THE constant regular determination of flue gas analysis will enable every Canadian engineer to accomplish the following results:

1. Improve methods of handling fire.
2. Improve draft regulation.
3. Detect air infiltration.
4. Indicate necessity, if any, to provide secondary air supply.
5. Indicate needed changes in design and construction of furnace.

In addition, the installation and regular use of flue gas analysis apparatus in a boiler room increases the morale of the entire "crew." Efficiency is infectious. Being stimulated to employ better firing methods, the men will handle every part of their work in a better and more economical manner.

No One May Know

Thin fires through which holes quickly develop insure low CO_2. The fireman cannot always tell by inspection when his fires are too thin. He may be careless, and if there is no check on CO_2 no one may be any the wiser.

There is no such thing as a fixed adjustment in the operation of a boiler. Load conditions vary and the rate of combustion must follow suit or the steam pressure will drop. This calls for variations in the thickness of the fire, and these variations cannot be made anything like as correctly without CO_2 equipment as with it.

With hand-fired boilers a continuous CO_2 record shows how often the fires were replenished, how long the fire doors were left open, when fires were cleaned, and how long it took to clean them.

In stoker fired boilers equivalent changes are indicated.

Improve Draft Regulation

Unnecessarily high drafts decrease the percentage of CO_2. On a recent test of a boiler burning No. 1 Buckwheat, a fairly uniform relation between the boiler draft and the amount of CO_2 was indicated. With a draft of 0.20" a CO_2 content of eight per cent. was found. Reducing the draft to 0.18 increased the CO_2 to nine per cent. A further drop in draft to 0.16" produced a ten per cent. CO_2. Cutting the draft still further to 0.14 an eleven per cent. CO_2 was established. With a draft of 0.12" the CO_2 content was increased to twelve per cent.

Here the improvement ceased. A further drop in draft resulting in a decrease in CO_2 showing that for the particular load demand and the particular condition of the fuel bed during the test a draft of 0.12" was most economical.

With another fuel and under other conditions a different draft would be required. The economical draft can be more readily determined with the aid of CO_2 analysis apparatus than in any other manner.

Detect Air Infiltration

The presence of leaks permitting the infiltration of air into the setting through the brick work or doors can be detected readily by means of CO_2 apparatus. If the percentage of CO_2 is not increased by better handling of fires or by adjusting the draft then it is time to examine the setting.

A lighted candle passed slowly over the brick work and door joints will indicate air infiltration as the flame is sucked in.

Each pound of fuel of a certain composition requires a certain fixed weight of air for complete combustion. In addition to this fixed amount an additional percentage of excess air must be provided so that despite faulty distribution of the air supply there will be a particle of oxygen available for each particle of carbon or other combustible to be consumed.

Whether the amount of excess air is high or low determines boiler efficiency. As the amount of excess air is measured by the percentage of CO_2, we can determine by the use of CO_2 indicators whether we have an adequate supply of air, properly distributed.

Insufficient combustion space is another direct cause of low CO_2. If we have carefully checked over our firing methods, draft regulation, condition of our settings and air supply and if we still find that we are getting low CO_2, it is time to examine furnace design and furnace volume. Hundreds of furnaces are re-constructed every year to the profit of the owners, as a result of the findings of CO_2 indicators.

The loss due to heat carried away by dry chimney gases for varying percentages of CO_2, and different temperatures of exit gases is shown in Fig. 1 and Fig. 2. Fig. 1 shows the actual loss in B.t.u. Fig. 2 shows the percentage loss of the total value of the fuel, based on a coal of 14,000 B. t. u. Table 1 gives a rough approximation of the per cent. loss up the chimney for the several major classes of fuel.

CO_2 Indicators

A great many different types of apparatus have been developed for indicating and recording CO_2. In describing and illustrating a number of these, we do not impute any lack of merit to makes of apparatus not mentioned, or only described briefly.

The orsat, Fig. 3, is employed for volumetric analysis of a single sample. The principles employed in the equipment illustrated are used in practically all of the portable appliances on the market. A measured sample of gas having been drawn from the stack, is forced successively through pipettes containing solutions of caustic potash, pyrogallic acid, and cuprous chloride in hydrochloric acid, respectively, thus absorbing the carbon dioxide, the

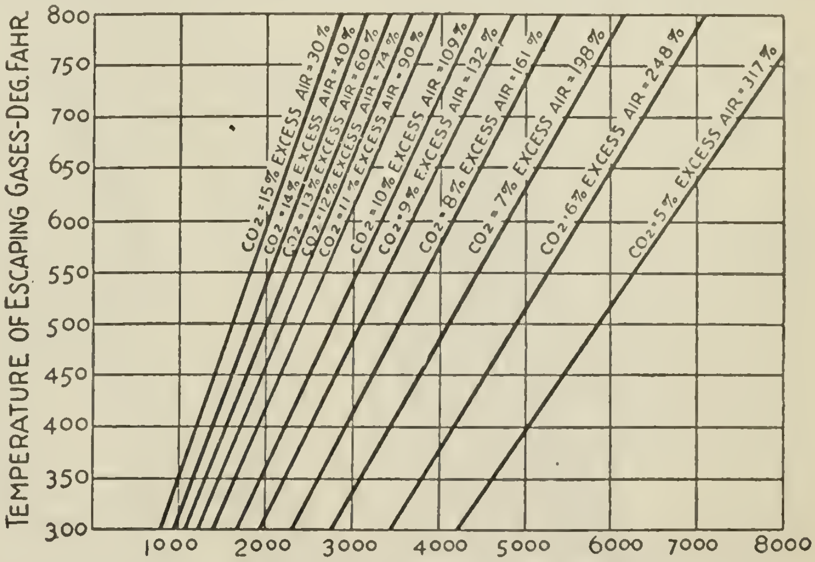

Fig. 1—Losses occurring with various percentages of CO_2

oxygen and the carbon monoxide, the contraction of volume being measured in each case. The original orsat apparatus is bulky, fragile and slow, but it is accurate. Some recent modifications have considerably improved the apparatus. There is room for an orsat in every power plant for the following services:

1. To determine the maximum CO_2 which can be carried while still securing complete combustion.
2. To inspect settings for air infiltration.
3. To check up the continuous CO_2 recorders.

By itself the orsat is inadequate as a control for the firing operations of a boiler plant. It is decidedly better than nothing however and as it is not expensive it should be employed in every plant whether CO_2 recorders are installed or not.

Sarco CO_2 Recorder

One inch pipes tap the side flues or last combustion chambers of the boilers or furnaces, and a three-quarter inch main pipe from them is connected to the instrument. In order that the gas samples may be secured rapidly and continuously, the circuit is completed by another pipe of the same diameter. This is carried to the base of the chimney or, where this is not practicable, to a convenient point in the main flue, well beyond the boiler damper. Thus a continuous, rapid passage of the gas is secured, which, usually, renders it possible to read on the chart the effect of an alteration in the firing within two or three minutes of its occurrence.

The instrument, once erected, works entirely automatically, and requires little attention beyond changing of the chart every 24 hours, and renewal of the potash solution every fourteen days to three weeks.

Foxboro CO_2 Recorders

In the Foxboro recorder a solution of caustic is used for a re-agent. The motive power is obtained from a constant flow of water and the periodic operation of an automatic syphon, the amount of water required per day being approximately two barrels. There are only three moving parts—the clock movement for rotating the chart, the pen-actuating float, and the dotting mechanism.

The operation of this particular machine is as follows: The water flows through the coils into a measuring vessel and traps a definite volume of gas in a bulb, forcing it over through a tube to an absorption vessel, where it bubbles up through caustic solution, which almost instantly absorbs the CO_2 gas present. Above the caustic solution is a layer of oil, and above that is a gas chamber. A float tube terminates in a tube which extends through the oil almost to the level of the caustic solution. Pressure in the chamber causes the oil to flow through the tube into a float tube which encloses a float, to the upper end of which is fastened a pen.

The distance the pen will rise depends upon the quantity of gas forced into the gas chamber by the rising water— the gas reaching the gas chamber being residue of the original sample after CO_2 is removed. The water rising in the water-float tube raises a float which operates dotting mechanism, causing the pen to press against the chart.

The water now syphons out, and, as the syphon takes water away faster than it is delivered, the float drops, releasing the pen. As the water continues to syphon out, the pressure in the gas chamber decreases and eventually balances to atmospheric pressure through the exhaust pipe, the float in the tube dropping to normal position.

Water passing through the syphon operates an aspirator, creating suction through a water seal, and drawing flue gas through the chamber of the filter. Part of this gas is drawn through the filter into the measuring vessel through an intake pipe. When the syphon breaks, the pressure of the gases in the measuring vessel balances, and the cycle is resumed by the rising water trapping the unit quantity of gas in the bulb.

Uehling Apparatus

The principle involved in the operation of the Uehling CO_2 meter depends upon the change in pressure in a stream of gas flowing through two apertures, caused by absorption of its CO_2 content. The apparatus consists of three principal parts, namely the CO_2 meter proper, the recorder for the engineer's office and the auxiliary boiler front indicator for the fireman. The CO_2 is extracted, in the CO_2 meter proper. The CO_2 meter, in turn, actuates the recorder and indicator.

TABLE I.

Heat Loss With Various Percentages of CO_2 for Different Fuels.

Per Cent. CO_2	Carbon	Anthracite Coal	Bituminous Coal	Fuel Oil
	Loss	Loss	Loss	Loss
3	67.2%	61.8%	58.1%	49.4%
4	50.5	47.1	44.6	38.9
5	40.7	38.3	36.5	32.6
6	34.0	32.3	31.1	28.4

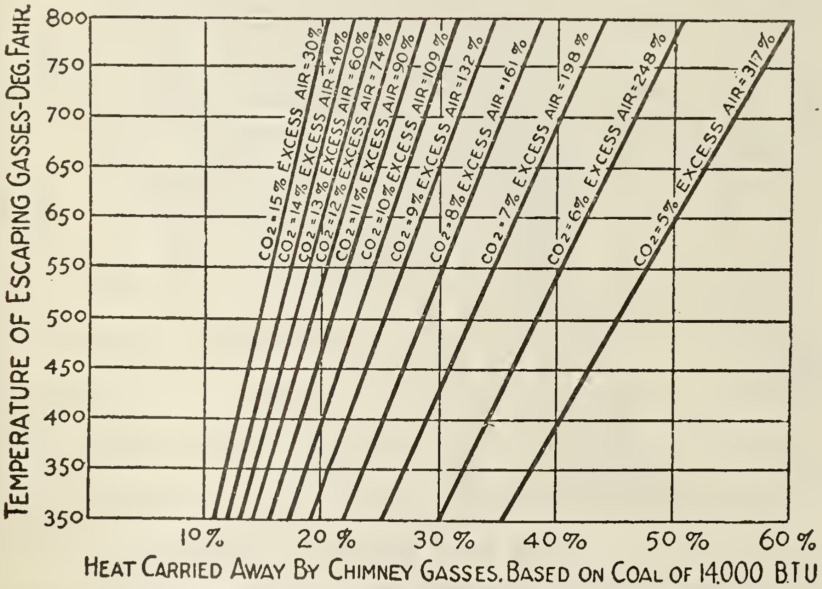

Fig. 2—Percentage of Heat Lost With Various CO_2 Percentages.

Republic CO_2 Recorder

The Republic depends upon the flow of water for its operation. It is so constructed that a variance from a minimum supply to a full open valve will not affect its proper functioning. The gas is drawn from the furnace to the instrument by means of a water jet and aspirator. It is a chemical machine.

Precision CO_2 Recorder

This instrument is likewise operated by a small stream of water. Individual gas samples are taken, analyzed with the aid of chemicals and the results recorded. After one sample has been analyzed another is taken immediately and duly recorded.

Hays CO_2 Recorder

In the operation of the Hays CO_2 recorder, a continuous stream of gas is drawn rapidly from the last pass of the furnace and at regular intervals the machine takes a measured sample of this gas, causes the CO_2 to be absorbed by means of caustic potash (KOH) solution and the pen to move on the chart to a point representing the per cent. by volume of CO_2 contained in it. Such variables as temperature and pressure of the gas sample, evaporation of water and changes in the specific gravity of the KOH solution are automatically controlled by the machine.

Water from the regular source furnishes the motive power for this type of recorder; about one gallon is required for each operation. This flows into the aspirator and thence into the overflow box. The speed of operation is governed by the amount of water admitted to the recorder through the sliding sleeve regulating valve. The range of adjustment is from one to four minutes, but a cycle every two and three-fourths minutes is recommended.

Electrical CO_2 Meter

The S. & H. CO_2 meter, (Bachrach) operates on a principle entirely different from that of the chemical CO_2 indicator; it makes use of the physical property of heat conduction of the gases. An electrical system is arranged in a Wheatstone bridge circuit, of which four branches are four platinum wires in two blocks. Across the mid points of the bridge is connected a sensitive indicating galvanometer. If desired the recording galvanometer, which may be placed at any reasonable distance from the measuring instrument, can also be connected into the circuit. The electrical energy is obtained from a small storage battery through a variable resistance which is adjusted to give constant current through an ammeter.

The flue gases consist of carbon dioxide, (CO_2), carbon monoxide, (CO), oxygen, nitrogen, and water vapor, with traces of other gases. Nitrogen, oxygen, carbon monoxide and air all have practically the same heat conductivity, but CO_2 has 40 per cent. less conductivity, and water vapor a conductivity about 30 per cent. greater than that of air.

The air in the comparison chamber is kept free from water vapor by the presence of hydroscopic chemicals, and the flue gases having passed through a cooler which also acts as a dryer, contain a very small, but practically constant, quantity of water vapor, hence the only variation occurring in the heat conductivity of the gases depends directly on the percentage of CO_2 in the flue gas.

As the electric current flows through the platinum wires, the heat which is generated in them is transmitted through the gases to the walls of the chambers.

Arndt Gas-Balance

The action of the Arndt apparatus is based upon direct measurement of the weight of the gases, CO_2 being heavier than air. In the absence of moisture, and at a fixed standard of temperature, the variations in density serve as an index of the CO_2 contents of the gases. The scale of the balance is graduated, so that the percentage of CO_2 can be read off directly. With a recording attachment of the usual type, a permanent record of the variations is obtained.

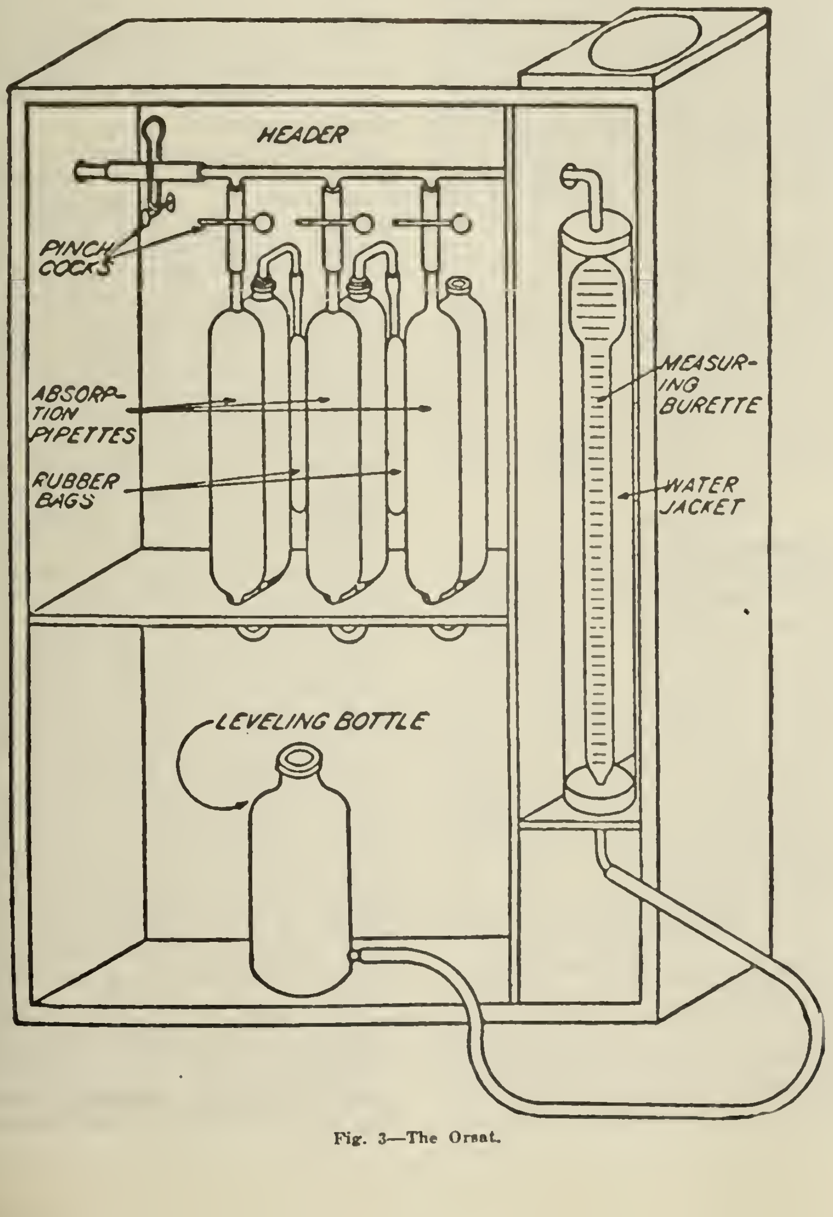

Fig. 3—The Orsat.

Krell CO_2 Recorder

This instrument is closely allied to the Arndt Gas-Balance. A very delicate differential pressure-gauge is employed to determine the difference in weight, of measured volumes of the flue-gas and air; and is attached to two columns of equal height, the one containing air and the other the sample of flue-gas.

A slightly inclined glass tube, filled with colored alcohol, is employed to record the pressure-gauge reading. The height of this thread of colored alcohol varies with the pressure, and by means of a scale marked in the percentages of CO_2, corresponding to certain pressures, the amount of this constituent of the flue-gas can be read off.

Haber-Loewe Refractometer

This instrument depends for its action upon measurements of the "refractive index" of the mixed gases. The method is thus an optical one, and resembles the optical methods for determining temperatures. The refractometer consists of the following three parts:—a prism, a telescope and a microscope.

The prism made of varnished metal, is provided with windows on opposite sides for the incident and reflected rays of light to enter and escape—and the gas to be tested flows through it, while the gas used for comparison flows through the casing. The observer sees in the field of vision when using this instrument, a scale which is partly illuminated and partly in darkness. The boundary of the dark zone will coincide with zero on the scale in pure air. In air containing nine per cent. CO_2 this boundary will coincide with 1.0 on the scale; and the line of demarcation between the light and dark zones will be still further shifted, for higher percentages of CO_2.

The instrument can be graduated, however, to yield the percentages of CO_2, or some other gas, directly by observation.

Checking Analyses

The heat balance itself is always a good check on the accuracy of the results of a boiler test. The radiation and unaccounted-for losses are always determined by difference. If this item is larger or smaller than the conditions would warrant, judging from experience, then an error has been made either in the observed or calculated data. This may be due to the gas sampling tube not being located properly or to some error in the analysis, either from a faulty instrument or technique.

In order to check out on the results of an actual test, Prof. Thomas G. Estep worked out the following concrete example based on data taken from the report of a boiler test.

Protective Gear Minimizes Transformer Faults

By S. AUSTEN STIGANT, A.M.I.E.E.

A Brief Review of Modern Methods to Protect Electrical Systems From the Effects of Faults in Static Transformers With a Description of the Principal Types

WHEN we refer to transformer protection, precisely the same interpretation is to be placed upon the phrase as when referring to alternator protection; that is, the protection is afforded to the system and the remaining plant connected to it, against faults, for the latter can only be procured through special care in design, manufacture and operation.

The faults which may arise in transformers to perturb Canadian engineers and against which protection is required are:—

1. Earth faults and faults between phases.
2. Faults between turns.

The protective gear installed must ensure the complete disconnection of the transformer from the supply immediately a fault occurs in it, while such disconnection must not interfere with the continuity of service given by any sound transformer. The damage which is likely to occur to the transformer itself and to other parts of the system must be reduced to a minimum in the one case and entirely obviated in the other. The various types of protective gear outlined in this review generally succeed in fulfilling these requirements.

Faults Between Phases

In the following discussion it will be assumed that on the primary side of the transformer either the transformer neutral is earthed or the neutral of the system to which it is connected is earthed at some point other than at the transformer; it will also be assumed that the L. T. neutral point of the transformer is earthed. It will further be assumed that the protection is applied so as to embrace the connections between the transformer windings and the busbars on both primary and secondary sides.

The principal types of protective gear used in England to-day for transformer protection are:—

(a) Core balancing system.
(b) Merz-Price circulating current system.
(c) Merz-Beard self-balancing system.
(d) McColl circulating current system.

Core Balancing System

The application of the core balancing system of protection is shown in its simplest form in Fig. 1, as applied to a single-phase transformer, from which it will be seen that the system consists essentially in taking the main leads on each side of the main transformer through the core opening of a protective current transformer, the secondary winding of which is directly connected to a relay coil. The relay contacts on primary and secondary sides of the main transformer are connected in parallel, as also are the oil switch trip-coils, while for D.C. tripping a battery is connected in between the relay and trip-coil leads as shown in the diagram.

In order that the transformer shall not be tripped out of circuit by a distributor fault, the earth connections from the transformer midpoints must also be taken through the core openings of the protective current transformers; when this is done, fault current flows in one direction only through the current transformer in the case of a transformer earth fault, thus disturbing the balance of the system and operating the protective gear. The protective gear may be operated by a fault on either side of the transformer.

As in many cases, however, particularly with poly-phase transformers, it may not be permissible to earth the neutral, while in other cases the H.T. neutral on the transformer may be not available, the application of this system to transformer protection is distinctly limited.

The system is applicable to earth fault protection only and not to protection against faults between phases. Fig. 2 shows the system applied to a three-phase transformer with star connected windings, and it will be seen that in this case also, one protective current transformer only is required on each side of the main power transformer.

Merz-Price System

The Merz-Price circulating current system has, up to the present, enjoyed by far the greatest popularity of all the transformer protective systems which aim at the automatic disconnection of a transformer upon the occurrence of either an earth fault or a short-circuit between phases. The application of the system to the protection of a single-phase transformer is shown in Fig. 3.

The principle upon which the system is based is the equality of the currents at the two ends of a sound balanced circuit. When, however, the electrical continuity of a circuit is interrupted by a static transformer for the purpose of pressure alteration, the currents on the two sides obviously are not equal in the mathematical sense, though at the same time by suitably designing the protective current transformers they may directly be compared.

In a sound balanced system the currents flowing into and out of the circuit are the same or directly comparable neglecting losses, but if an earth fault or short-circuit between phases occurs this equality is disturbed and the difference in the amounts or ratios of entering and leaving currents is utilized for tripping the faulty apparatus out of circuit. With Merz-Price circulating current protection for a three phase star/star transformer protective current transformers are inserted in series in each line on both H.T. and L. T. sides, designed so that the secondary currents of the current transformers on the H. T. side are the same as the secondary currents of those on the L.T. side.

The current transformer secondaries are connected so that the normal currents in them flow in the same direction round the secondary circuit composed of the windings and the short pilot cable connections. Relays are connected to equipotential points between the current transformer secondaries, and, with them so connected, there is no tendency for current to flow through the relays under normal operating conditions. If, however, an earth fault between phases occurs in the main transformer the currents in the current transformer secondaries will differ in magnitude or phase (or both) and this difference flows through the relay windings, thereby operating the automatic oil switches. The current transformers are of the ordinary switchboard type, and, as in practice it is difficult to obtain exact balance on heavy overloads, too fine a relay setting should not be adopted; the relays should be set to operate at a current somewhere between fifty per cent. and 100 per cent. higher than the minimum current at which they would operate.

If fuses are inserted in series in the pilot wire connections between current transformer secondaries, the protective gear will operate on overloads as operation of the fuses leaves one set of current transformers only connected to the relays, and consequently the secondary currents must flow through the particular relays, so operating the oil switch. These fuses are designed to operate at currents between five amps. and ten amps., according to individual requirements. In order to prevent operation of the relays when switching a transformer into circuit, it is usual to provide so-called "kick" fuses to shunt the relay terminals, thereby short-circuiting the magnetizing current rushes when switching in the transformer.

These fuses are set to operate at currents corresponding to about seventy-five per cent. of the full-load current, while the relays operate at currents of the order corresponding to seven and a half per cent. to ten per cent. of the full-load current. These kick fuses should be short-circuited after the transformer has been switched in, as their permanent insertion would necessitate relatively coarse settings of the relays for the actual operating conditions and so decrease the sensitiveness of the protective system.

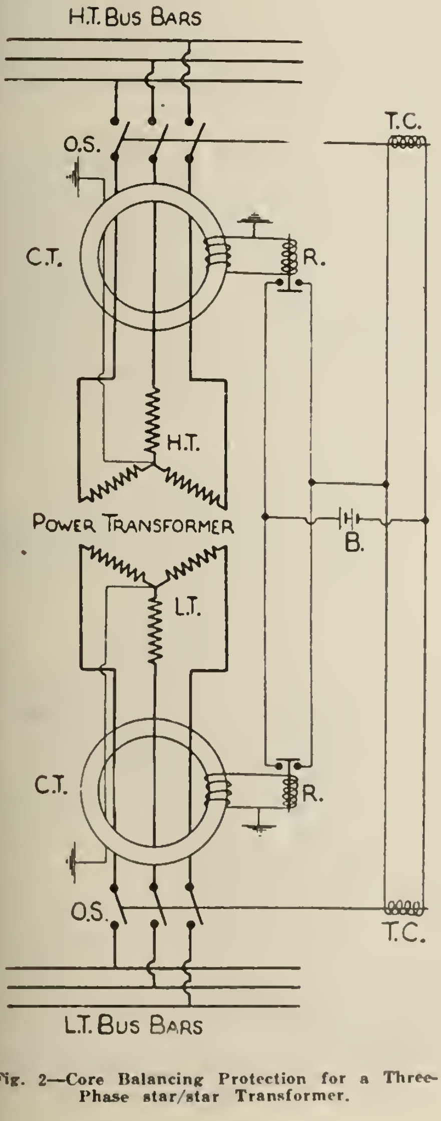

Fig. 2—Core Balancing Protection for a Three-Phase star/star Transformer.

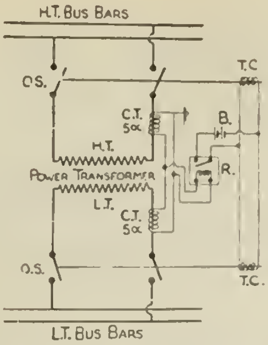

Fig. 3—Merz-Price Circulating Current Protection for a Single-Phase Transformer.

When the Merz-Price circulating current system is applied to a delta-star connected three-phase transformer the secondary connections are the same as those previously described except that the current transformer secondaries on the star-connected L.T. side of the main transformer are connected in delta in order to compensate for the phase displacement between the current in the lines on the primary and secondary sides of the main transformer.

In this case the current transformer secondaries on the L.T. side of the main transformer are designed for a secondary current of fifty-eight per cent. of that taken by the secondaries of the current transformers on the H.T. side of the main transformer, as on the L.T. side each current transformer secondary carries a delta current, while on the H.T. side the secondary of each current transformer carries a star current, and the star lines current of the two groups of current transformer secondaries must be the same.

In those cases where, due to the position of the current transformers and the run of the pilot cable, it is difficult to obtain equipotential points on the latter, balancing resistances may be inserted in series in the pilot wires between the current transformer secondaries, and equipotential points for relay connections may then be obtained at places other than midway between the current transformer secondaries, according to the location of the balancing resistances.

Self-Balancing System

The application of the Merz-Beard self-balancing system of protection to a single-phase transformer is shown in Fig. 4, and to a star/star connected three-phase transformer in Fig. 5. The principle involved is the comparison of ingoing and outgoing currents separately on each side of the main transformer. The two ends of each H.T. and L.T. phase winding are both taken through the core opening of a common protective current transformer so that, as the currents in the two leads passing through each core flow in opposite directions, there is no magnetic flux in the cores of the current transformers under normal operating conditions. If, however, an earth fault occurs in the transformer or if a breakdown between phases occurs, the current balance is destroyed and the resultant currents produce magnetic flux in the cores of one or more of the current transformers, so that a tripping current flows in the secondary circuit to energize the relays and operate the automatic oil switch.

This scheme gives a closer degree of protection than the ordinary Merz-Price circulating current system, and as there is no balancing of protective current transformers against each other, the question of ratio accuracy at heavy overloads does not arise; the current transformers can, therefore, be used over a wide range of primary currents. With this system the fault current setting of the relays is not dependent upon the actual value of the out-of-balance current for providing sufficient power to operate the relays, but it is fixed by a current difference.

The system is really an application of the split conductor system of feeder protection, and its only disadvantage lies in the fact that it is necessary to bring out both ends of all phase windings. Pilot wires between current transformers secondaries are not required, it being necessary only to interconnect the relays as shown on the diagrams.

Except for the meshing of the windings of the main power transformer the diagram in Fig. 5 is exactly the same for other combinations of three-to-three-phase (main transformer meshing that is, for delta/delta, delta/star, etc., as in all cases the ingoing and outgoing currents of each phase and on each side are directly compared with one another. The protective current transformers are designed individually to give five amps. on the secondary, and this holds good quite irrespective of the meshing of the main transformer windings.

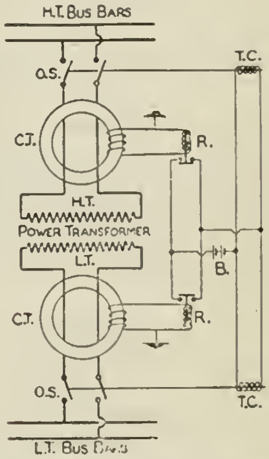

Fig. 4—Merz-Beard Self-Balancing Protection for a Single-Phase Transformer.

McColl Current System

While the Merz-Price circulating current system is inherently a sensitive protective scheme, full advantage cannot be taken of this on account of the unstable characteristics of the protective current transformers under severe overload conditions, such, for instance, as the passage of short circuit currents through healthy apparatus to remote parts of the system. In actual practice the unstable tendency may be due to a faulty choice of equipotential points and to vector unbalancing of current transformers, which becomes accentuated when the induction density in the cores reaches high values under fault conditions in other parts of the system.

As a result of these aspects the relay settings must necessarily be high, in order to ensure stability, and in practice the fault settings average about thirty per cent. or more.

A development of the circulating current system has been put forward by A. E. McColl, an English engineer, in which biased relays are employed, Fig. 6 showing the application of the system to a star/star connected three-phase transformer and Fig. 7 to a delta/star connected transformer.

The relays are of the mechanically biased beam type, one coil being traversed by the main current in the secondary system and the other coil being connected to equipotential points, one of which, in this instance, is midway along the restraining coil. If a bias corresponding to, say, a ten per cent. fault current is desired, the restraining coil would be wound with approximately ten per cent. of the number of turns in the operating coil, and under this condition the relay would definitely be held in the off position until the unbalanced currents flowing through the operating coil reach a value equal to ten per cent. of the current flowing through the restraining coil. At these values the ampere turns of the respective coils would balance one another.

With this arrangement it is possible to give a definite degree of stability under the abnormal operating conditions which should not trip the particular transformer out of commission, as ample latitude for unbalancing of the protective current transformers may be allowed. This system is operative for transformer earth faults between phases.

A further development, also due to McColl, of the biased relay circulating current protection as applied to a delta/star connected three-phase transformer is shown in Fig. 8. In this particular scheme the so-called reactive type dynamometer relay is employed having its elements shunted by a resistance. Under normal conditions the circulating current flows straight through the two coil elements of the relay and through the shunt resistance, the direction of the currents being such that the relays remain unbiased. If an earth fault occurs on one phase, the corresponding fault current in the secondary circuit will flow along the equipotential lead and through element No. 2 of the relay, and as the fault current through this local circuit increases, the main circulating current diminishes through element No. 1 of the relay, and increases through the shunt resistance.

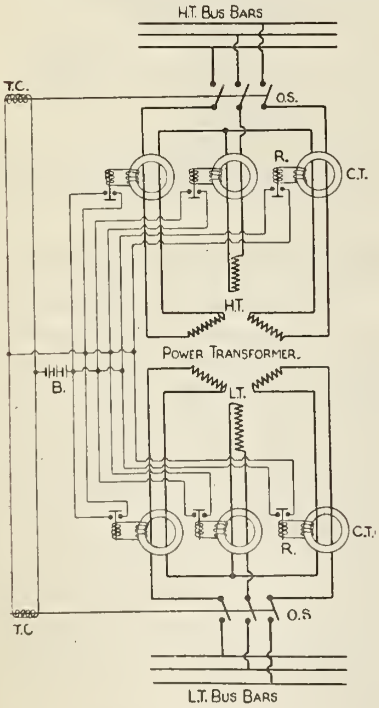

Fig. 5—Merz-Beard Self-Balancing Protection for a three-phase star/star transformer.

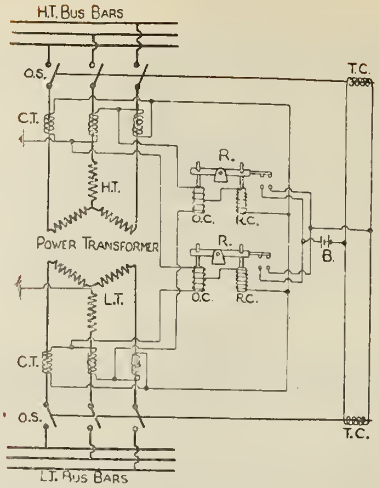

Fig. 6—McColl Circulating Current Protection using Biased Beam Relays, for a three-phase star/star transformer.

Ultimately the fault current reaches such a value that the whole of the main circulating current is forced into the shunt resistance, and no current flows in element No. 1 of the relay. Further increase of fault current causes a portion of it to flow through No. 1 element in the reverse direction and thence through the shunt resistance, reversal of current flow through one element constituting the condition necessary for operating the relay. The operation of the relay does not take place until all the main circulating current is forced into the shunt resistance, this point determining the bias of the relay.

The point at which reversal takes place through one element may be controlled by varying the ratio of the ohmic value of the relay elements and the shunt resistance. The system is similarly operative for a fault between phases of the transformer.

Faults Between Turns

Dealing next with the question of protection against the effects of faults between turns in a transformer, it can be stated that these usually occur in the H.T. windings, and, therefore, it is only necessary as a rule to instal protective gear on the H. T. side. When, however, the L.T. side of the transformer is wound for a pressure which is really a high pressure, say, 6,600 volts and above, the protection should, to be consistent, be applied to the L.T. side also. In such a case the two transformers to be protected would have to be connected in parallel. The scheme now proposed for isolating faulty transformers in the incident stages of a fault between turns is termed the midpoint protective gear. The protective gear is applied to the H. T. windings only, and for the application of the scheme it is necessary to have a second transformer or a potential transformer connected to the same H.T. busbars for the purpose of obtaining equipotential points. The protection then, of course, applies to both transformers.

The H.T. windings are provided with tappings at the midpoint of each phase, these midpoints being connected together through suitable protective current transformers, while the secondaries of the current transformers are connected to relays. Under normal conditions, the midpoints which are connected together are at the same potential, and, therefore, no currents flow in the midpoint connections. If, however, a short circuit between turns takes place in the H.T. windings of either transformer the number of turns active between the midpoint and the particular end of the phase winding concerned will be less than those normally active, and, therefore, the potential of the midpoint of the faulty phase will be different from that of the midpoint of the corresponding phase on the sound transformer. Current will, therefore, flow in the midpoint connection from the faulty phase, and the corresponding current in the secondary winding of the protective current transformer will operate the tripping relays.

This system also gives protection against faults to earth and between phases occurring in the transformer windings, but it does not protect the transformer leads unless the cables are provided each with a conducting sheath surrounding the core and insulated from the core and from the sheath for half the phase pressure. This conducting sheath should be connected to the transformer midpoints.

Location of Fault

The location of a fault between H.T. and L. T. transformer busbars is determined by methods somewhat similar to those employed for the detection of alternator faults, that is, either by megger tests or by pressure tests with a testing transformer. Usually, however, when by a process of elimination, the fault is found to be in the transformer, it will in most cases be appar-

(Turn to Page 55.)

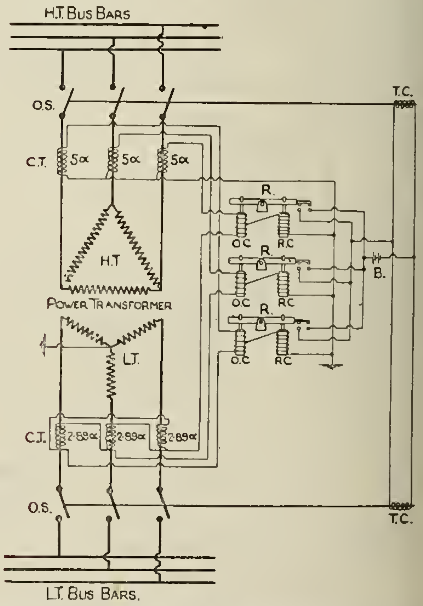

Fig. 7—McColl Circulating Current Protection of same type as Fig. 6 for a three-phase delta/star transformer.

Lubrication and Its Effect on Steam Boilers

By EDWARD L. GROSS*

The Quality of Oil Used in the Engine is Usually of Paramount Importance in the Operation of the Steam Generator or the Steam Boiler Itself

THE lubrication of steam-driven units, both of the reciprocating and steam-turbine type, has been reduced to a pretty exact science. Knowing the type of engine, load to be carried, revolutions per minute, temperature of steam, etc., the character of lubricant to be employed can be definitely determined by those versed in the art. It is not, therefore, the purpose of this article to discuss this particular phase, but to bring to your consideration the relation of the steam boiler itself to the lubrication problem.

Not only do certain phenomena occurring in the steam boiler materially affect engine lubrication, but in turn the lubricant employed in the engine itself plays an important role in the operation of the steam generator or steam boiler itself.

Exhaust Contains Oil

In studying the efficiency of the various types of steam engines, it is found that, with a very few exceptions, all of the steam that is exhausted from them contains oil that has served its useful purpose as a lubricant, and if the steam is condensed and returned as boiler feed water, considerable of this oil gets back into the boiler and is capable of doing considerable harm.

One of the advantages possessed by the steam turbine, as compared to the reciprocating type of steam engine, is that when it is operated condensing, no oil gets into the steam passages. A surface condenser can be employed in connection with the turbine and the condensate returned to the boilers practically free from lubricant, without the necessity of oil separators.

Oil in a steam engine is a mighty good thing, but oil in a steam boiler is a mighty bad thing.

Insulating Power of Oil

It has been estimated that the insulating power of a thin film of oil on the heating surface of a boiler is much more than that of a scale averaging one-sixteenth of an inch in thickness. In addition, the scale that is formed by the collecting of light floating material by the surface film of the oil and its settling on the heating surface is even worse than ordinary scale, because, in addition to causing a loss of heat, it also causes corrosion of the metal.

One would naturally infer, in view of the fact that oil is lighter than water, that it would remain on the surface, but this is not the case. As above explained, the oil comes in contact with the small particles of lime, magnesia, etc., and by sticking to them soon becomes as heavy as the water, with the result that it is carried around by the circulation, and, coming in contact with the metal, sticks to same.

This explains why the under side of the boiler tubes are just as liable to become encrusted with a mixture of encrusting salts and oil residue as the upper side.

The insulating effect of a thin film of oil on the heating surface is surprising. A recent test showed that with fire temperatures ranging from 2,190 deg. to 2,500 deg. Fahr., the temperature of metal at the bottom of an iron vessel, ½ in. thick, when the surface was clean, was 280 deg. Fahr. On mixing 5 per cent. mineral oil with the water it rose to 310 deg. Fahr., and when the bottom of the vessel had a coating of grease 3/64 in. thick, it rose to 518 deg. Fahr.

Two men with the aid of mechanical stokers can handle a boiler room that would require five men if it were hand fired. This means a marked reduction of labor costs, of course, but the saving of labor is of no greater importance than the solution of power plant labor problems by the use of mechanical stokers. The better labor conditions offered by the stoker fired plant make a strong appeal to a better class of men—men who keep their jobs and take a pride in their work. All of the distasteful boiler room duties are practically eliminated by stoker firing. The slicing of fires and cleaning of fires, are automatic functions of the mechanical stoker. Fewer men are needed; a better class of men is attracted to the plant.

Mineral oils form a coating similar in appearance to brown varnish when deposited on a boiler-plate, forming a coating which readily results in overheating of the metal and burnt and bagged sheets.

Crude Oil for Scale

It is a rather peculiar state of affairs that in spite of the fact that power plants spend a large amount of money in installing fairly efficient oil separators in the exhaust steam line, and in spite of the harmful effects of oil films on heating surfaces, engineers in certain plants still employ crude oil as a boiler scale preventive and for the purpose of stopping boiler foaming and priming.

In reference to the corrosive action of scales containing oil, it can be readily seen that the oil could only be chemically active insofar as its compounding was concerned, as the average cylinder oil contains between 2 and 10 per cent. of organic compound. Under the high temperature prevalent in steam boiler practice, these animal and vegetable oils are decomposed with resultant formation of organic acid, with consequent pitting and corrosion of the plate.

It would appear to the writer, therefore, that in compounding oils some consideration should be given as to whether or not the engine in which they are to be employed runs condensing or not, and if the former is the case the oil should be prescribed, other things taken into consideration, with the minimum compounding.

Terms Often Confused

The effect of oil in a boiler and the effect of the boiler on the oil in the engine is intimately related to that common trouble known to engineers as foaming and priming, and which terms are very often confused.

Foaming consists of the steam bubbles building up upon the surface of the water instead of breaking and releasing steam. It only becomes serious when the bubbles form so rapidly and hang together long enough to reach the point where the steam is supposed to be taken off, when a sort of syphoning action takes place and a large amount of water is carried over entrained with the steam.

Priming, on the other hand, is due to a sudden evolution of steam from the heating surface, very similar to the so-called "bumping" which takes place in laboratory apparatus during distillation, and is due either to poor design of boiler, on a sudden demand for steam.

In some instances it is caused in boilers where the heating surface is covered with a heavy scale coating due to a sudden release of the incrustation from the metal, with the result that the water strikes the overheated surface with an extremely rapid generation of steam. The result is the same, namely, a carrying over of large amounts of water.

Priming is altogether different from foaming, and can be, to a considerable extent, controlled mechanically.

While the causes producing foaming have not as yet been at all definitely

Files Stokers

Hand Operated

Canada Faces a Fuel Shortage

Consider What Files Stokers Mean to You Under Such Conditions

CANADA is face to face with a serious fuel shortage. This situation is not new and you know how it affects your plant. How to meet this fuel shortage is the problem that vitally concerns you. You should strive to make the most out of conditions prevailing to-day, and which will continue to prevail for some time to come.

USE FILES HAND OPERATED STOKERS. THEY PROVIDE FOR MORE EFFICIENT BURNING OF FUEL

Boilers rating as high as 200 per cent. can, as a matter of fact, be carried on Files Stokers with natural draft.

Furthermore Files Stokers insure clean fires without the necessity of slicing or poking through the open fire-doors. To sift the ashes, clean the fires, break all clinkers and dump refuse into the pit, you only have to move convenient levers mounted on the boiler front.

Files Stokers save fuel and labor all the year 'round—under any conditions—fuel shortage or not. Investigate their possibilities in your plant.

Boilers Do Not Smoke!

WHEN you hear anyone say, "the boiler is smoking," this is not really what is meant. The expression is erroneous. Certainly, boilers do not smoke. It's the fire that smokes. What causes the fire to smoke? That's the question. In most cases smoking fires are caused by improper boiler setting.

Are your boilers properly set? It requires an expert to tell. We are ready to furnish the expert. No, we do not set boilers, but our engineering staff knows how a boiler should be set to operate to the best advantage. Our engineering staff is at your service.

May We Serve You?

Waterous
BRANTFORD, ONTARIO, CANADA

established, still it is a fact that large amounts of suspended matter in the boiler water and the presence of oil are sources of trouble in this respect. One of the most active salts producing foaming, however, is sodium carbonate, commonly known as soda ash, and which is employed in many power plants either in water-softening apparatus, or in boilers themselves for the purpose of removing and preventing scale formation.

Foaming and priming of steam boilers are directly related to the lubrication of the steam engine itself. As above explained, when these two phenomena or either one occurs, large quantities of water are carried over with the steam. Boiler water runs fairly high in salts, such as calcium and magnesium carbonates and sulphates, which naturally are carried over with the water. Due to their sandy or gritty nature, they naturally seriously interfere with lubrication of the engine cylinders.

These salts tend to combine with the organic constituent of the lubricant, forming insoluble soap, which greatly interferes with the efficient working of the lubricant itself, and results in the familiar sticking or groaning taking place in steam engines when foaming or priming of the boilers occurs.

When soda ash is employed in the boiler, quantities of this are also carried over with the steam, intensifying the harmful action of the salts themselves and cutting off from the rubbing surfaces the entire oil film, with the result that the piston may freeze or stick in place, with consequent serious damage to the engine.

In turbine practice oil is always contaminated with water, which leaks through the packing glands. In cases of serious breakdowns of turbine lubrication, examination of the emulsified oil has shown the presence of these salts carried over with the boiler water.

Many of the boiler compounds or chemical treatments employed in boilers for reducing the amount of scale forming on the heating surface run rather high in soda ash, and in many cases in caustic soda, an effective ingredient in causing a quick removal of oil film.

Foaming Easy to Stop

Foaming of boilers can be alleviated or prevented by various methods, and in particular by the use of an efficient anti-foaming compound which can be prescribed after intelligent study of conditions. It is not the purpose of this paper, however, to go into methods for overcoming this difficulty, or the protection of the engine from sudden carrying over of water.

To sum up briefly, therefore, in prescribing lubricants for steam-engine practice, some consideration should be given to the fact that quantities of the oil are apt to get back into the boiler with the condensate, and an oil prescribed which will prove to be the least harmful under these conditions.

Provision should be made in those plants where condensate is employed to see that efficient oil separators are installed in the lines to remove as much of the oil as possible, previous to the entrance of the condensate into the boiler.

Avoid Excess Lubrication

In those plants where foaming and priming are prevalent, careful investigation should be made by an expert to determine the causes thereof and to prescribe an effective remedy for preventing, or at least alleviating, this trouble. Where foaming and priming are due to improper boiler design or to extremely sudden demands for steam, a protective arrangement should be inserted in the steam line to protect the engine and turbine against interruption of efficient lubrication or possible complete wreckage of the engine or turbine.

The amount of lubricant for each individual engine which will give the most efficient working should be noted, and provision made to avoid excess lubrication or flooding of the engine, with consequent introduction of a large amount of oil into the steam boiler with the harmful results above noted.

Trade Catalogs

The Under-Feed Stoker Co. of Canada have recently published two bulletins, one illustrating the Arrowood system of pulverized fuel burning, the other the lateral retort under-feed stoker.

The Arrowood or "Multi-Mix" method of burning pulverized coal was developed by the Ground Coal Engineering Corp. A rotating screw delivers the pulverized coal to a space inside the perforated screen of a mixing drum. About 25 per cent. of the total air required for combustion is blown into the coal directly as it is whipped off by the screw, then the coal and the air pass through small orifices in the screen. The wire drawing is claimed to diffuse the particles uniformly in the air. These jets impinge against the outer shell setting up a mass of eddy currents. The jets of air and coal then pass into the main mixing part of the burner, where the remaining 75 per cent. of the air required for combustion is admitted. The air and the pulverized coal again pass through a series of orifices.

The mixing device is claimed to so thoroughly mix the air and the fuel that no excess air need be used. Other advantages claimed for the burner are low velocity of the air and the fuel entering the furnace, resulting in sufficient time for complete combustion and longer life for the boiler brick work.

The Jones "Lateral Retort" under-feed stoker was designed to meet the demand for a multiple retort, side cleaning under-feed stoker.

The stoker consists essentially of two multiple retort stokers placed back to back in such a manner that there is one main retort extending from the front wall to the bridge wall with the lateral retorts branching off this central retort at right angles. Coal from the main retort is forced into each lateral retort by means of lateral pusher blocks, operated by an auxiliary steam cylinder, independent of the main steam cylinder that operates the fuel ram feeding the coal into the main retort.

The advantages claimed for the lateral retort stokers are:—proper coal and air distribution, high efficiency combined with ability to carry heavy overloads, automatic control of the fuel and the air for combustion, agitation of the fuel bed, ease of repair when necessary, the use of plate tuyere blocks, and side cleaning, combining the simplicity of the single retort stoker with the flexibility of the multiple retort.

* * * *

The Bristol Co., Waterbury, Conn., have issued a bulletin No. 317 describing recording and indicating tachometers. The tachometers are for use wherever it is desired to know the speed of revolving shafting or machinery such as turbines, engines, line shafts, fans, etc.

The pneumatic instruments are made in the recording models only with records traced by ink.

The electric tachometers are furnished in both indicating and recording types. A magneto is belted to the machine or the shaft whose speed is being taken, wires connect the magneto with the instrument, allowing the instrument to be mounted at a convenient place. The round chart models use a direct marking smoked chart system for records, the advantage claimed being that friction is reduced to a minimum, resulting in a sensitive instrument. Where continuous records for a longer time than 24 hours are required the strip chart electric recording tachometer is used. Records are made in ink.

* * * *

The Brown Instrument Co., Philadelphia, distributed a pamphlet at the Chemical Show describing a new electric CO_2 recorder. The instrument works on the principle of the difference in thermal conductivity of various gases.

A Wheatstone bridge is the means used for comparing the thermal conductivity of the gas under test with that of another gas adopted as the standard of comparison. In practice one cell is filled with air and sealed for the comparison standard. The other cell is exposed to a flow of the gas under test. Since the thermal conductivity of CO_2 differs from that of air by approximately 40 per cent., it is possible to calibrate the equipment in terms of CO_2 percentage. Other constituents of flue gas such as carbon monoxide, nitrogen and oxygen have practically the same thermal conductivity as air.

The pamphlet contains several drawings showing the principles of operation and the method of installation.

Brown CO_2 recorders are made in indicating, recording and continuous recording types as well as a combination of CO_2 recorder and flue gas pyrometer.

Savings in Proper Control of Power Production

By CHARLES L. HUBBARD*

Greater Flexibility and Important Gains, Both in Economy and Capacity, May Often be Attained by Means of Comparatively Small Changes in the Boiler Room

MOST manufacturers have been giving their whole attention to the economical production of some special line of goods. They have been able, through long experience, to foresee future possibilities for enlarging the business; the improved processes necessary for securing desired results; the difficulties involved and the best methods for overcoming them.

Plants have been designed and equipped with special reference to production problems, improvements in processes, and reduction in labor costs. Those in charge have not hesitated to provide the best in the way of machinery, both for the handling of material and the manufacture of the finished product.

All work has been so managed as to reduce manual labor to a minimum, and wastes in material have been eliminated to the greatest possible extent.

Inferior Equipment

In view of this, it may seem strange that in most cases the power plant is far inferior to the main plant in matters of equipment and efficiency of operation, although it really should be considered as an independent manufacturing plant, whose output consists of power, heat, and light, all of which are of equal importance with the products of the main plant. Under the usual operating conditions the power department sells its output to the factory, so that the company operating the entire establishment benefits from both the selling and buying ends of the contract.

The typical power station, in most cases, is simply a factory for the manufacture of electric energy, and if steam-driven, can only utilize 15 per cent. to 20 per cent. of the heat contained in the coal burned under the boilers, the remainder disappearing mainly in the water discharged from the condensers.

Utilize Exhaust

In this respect, the industrial power plant has a great advantage over the central station, as a large proportion of the heat contained in the exhaust steam can be utilized for purposes which otherwise would require the burning of additional fuel.

Among the most important of these is warming the buildings, a requirement which continues from six to eight months in the central and northern sections of the country. In many plants large quantities of steam are required for process work throughout the year, and low-pressure exhaust may be made to fulfil this purpose in most cases.

In view of the fact that water powers are being rapidly constructed in many parts of the country, and that the conditions just described apply only to steam-driven plants, it might seem, at first thought, that the development of an efficient private plant was of secondary importance, as it might, at any time, prove more advantageous to purchase power from one of the central stations than to generate it upon the premises.

Outweighs Savings

While this might be true in certain cases, it is stated upon the highest authority that the cost of power generated by the average hydraulic plant will fall but little, if any, below that produced by steam, due to their greater cost of development and consequent high overhead charges, which balance, or overbalance, the saving in cost of fuel.

Charles L. Hubbard graduated from New Hampshire State College, a Bachelor of Science in Mechanical Engineering. He received his Mechanical Engineer's degree at Cornell after a year of post-graduate work in steam engineering. For some years he was connected with Brown and Sharpe Manufacturing Company and Holly Engineering Company, where he was engaged in the design and development of a new line of steam specialties. Then for twelve years he worked with Professor S. Homer Woodbridge of Massachusetts Institute of Technology as an engineer in charge of design and installation of heating and ventilating systems. The last few years he has been engaged in private consulting work in Canada and the United States.

This brings us back again to the statement previously made, that where steam is required for heating and process work, as well as for the generation of power, the privately operated plant may, in general, be run at a higher over-all efficiency than the largest and most up-to-date central station.

When put on this basis, the plant executive and the operating engineer should realize the importance of this part of the establishment, and the possibilities of increasing dividends by putting it in the very best condition possible. In order to do this effectively it will be necessary to get back to first principles, both as regards the equipment involved, its arrangement and operation.

The series of articles, of which this is the first, will take up the more important pieces of power-plant equipment and describe briefly the fundamental principles of construction and operation.

Different types will be considered, and attention drawn to points which should be noted in making a selection for any given set of conditions. The arrangement of apparatus in the plant, with reference to other pieces of equipment, will be discussed; and later, important matters bearing upon efficient operation.

While the average engineer or purchasing agent is more or less familiar with the principles and general construction of power-plant equipment, it will not be a waste of time to go over these matters and freshen up one's memory before taking up the more practical problems of selection, arrangement and operation.

Steam Plant Complex

While oil engines and hydraulic turbines will be considered in the series, the greater part will be devoted to the steam plant, because it is the most common and also the most complex.

The subject of steam itself will bear considerable study and will be taken up in a following article. The phenomenon of evaporation is important in boiler construction and operation, while the basic principle of the engine and turbine is that of changing a portion of the contained heat into useful work.

The condensation of steam and the giving up of its latent heat is applied to practical purposes such as in the warming of buildings and in various manufacturing processes.

A knowledge of the various properties of steam, as regards the quantity of unevaporated moisture which it contains, the degree of superheat, and so on, is important in order to secure the highest efficiency from engines and turbines, and also to guard against injury to these machines in its use.

Two Common Terms

Pressure and vacuum are common terms and well understood, but with the increase in both, in power-plant practice within recent years, it may be well to consider certain practical matters in connection with their application to boilers, engines, turbines, and condensers.

Following steam, we shall take up the subject of prime movers, which will include steam engines and turbines, oil and gas engines, and hydraulic turbines.

The economical transformation of heat into work by means of the conveying medium, steam, has brought about many changes in engine and turbine construction which should be well understood in making a selection for a given plant. It should be borne in mind, however, that conditions in the industrial plant are different from those where the economical generation of power is the sole object, and in certain cases an engine with a high steam consumption will give the more satisfactory results when both the power and heat requirements are taken into consideration.

---

*Consulting Engineer on Power House Problems. Reprinted in Canada by special permission from Factory, the Magazine of Management.

With automatic mechanical stokers it is often possible to use a cheaper grade of fuel, yet one which contains practically the same quantity of heat per pound. Fuels of this kind are uneconomical under hand stoking, due to the difficulty in handling, clinkering, and the large bulk of ash to be cared for.

When coal is stored in large quantities, care must be taken in piling it to reduce to a minimum the chances of spontaneous combustion.

Can Utilize Exhaust

For example, where all, or a large proportion, of the exhaust can be utilized throughout the year, a simple, slide-valve engine with a high water-rate will answer all purposes at a low first cost. In this case it simply acts as a pressure reducing valve for the heating system, and produces power at the same time at a small additional expense.

As the proportion of exhaust steam which can be utilized during the year becomes less, the importance of steam economy becomes greater, and a more efficient type of engine should be considered. Here power is the main product and low-pressure steam the by-product. Under these conditions, a Corliss or Uniflow engine would prove more desirable, and compounding might be considered as a means of reducing the water-rate still further.

The steam economy of the turbines of medium size does not vary materially from that of the reciprocating engine, when operated under the same conditions, and other details are usually the deciding factors between the two machines, such as space required, size and weight of foundations, and so on.

A Bleeder Turbine

When large quantities of low-pressure steam are required, and it is desired to keep the fuel expenditure as low as possible throughout the year, a bleeder turbine may be employed, and steam withdrawn from the intermediate stages whenever desired and in such quantities as may be necessary. As this machine is run condensing at all times, it operates at a good efficiency from the power standpoint and also serves as a reducing valve for the low-pressure steam required for heating and process work.

The power output from a plant using a non-condensing engine may be practically doubled without the installation of additional boilers by turning the exhaust steam into a low-pressure turbine connected with a condenser.

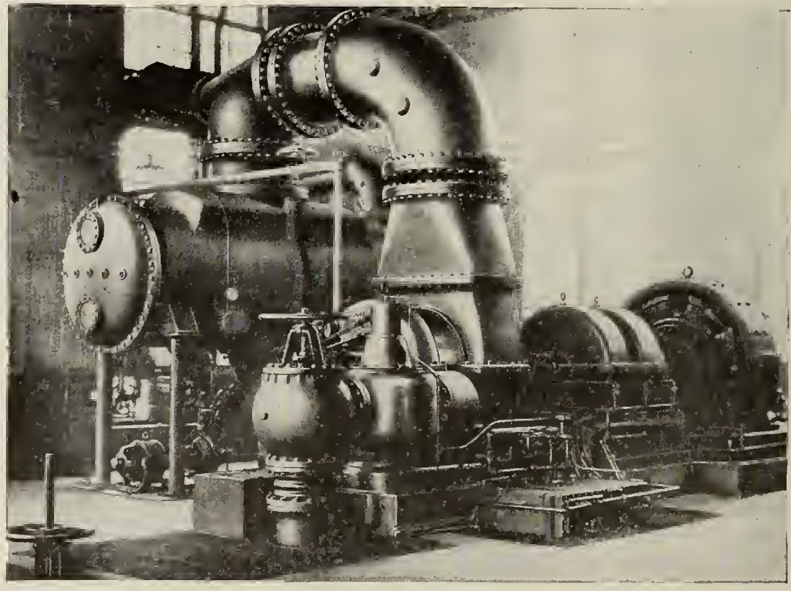
These are simple illustrations of how the economy of a plant may be increased when the requirements of the different prime movers, and the principles upon which they operate, are clearly understood.

Wasting Exhaust Steam

There are other cases where exhaust steam is produced in large quantities and where practically no requirements exist for heating and process work, as in forge shops, and so on. Here the exhaust from hammers and presses may be used to advantage either in low-pressure or mixed-pressure turbines, and the quantity may be still further increased by utilizing the hot gases from the furnaces which would otherwise be wasted. These gases may be passed through specially constructed heaters or boilers and the steam thus generated turned into the exhaust line from the hammers.

For low-pressure work of this kind, water for condensing purposes must be available at low cost in order to make the arrangement an economical one.

Waste heat from steel mills and free cement kilns has been used very successfully, and special boilers for this purpose

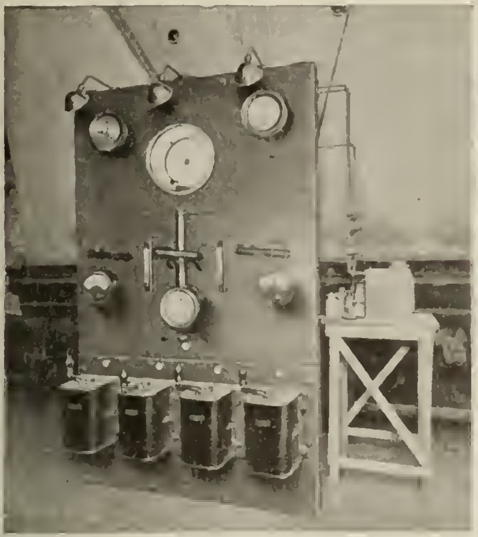


The power output from a plant using a non-condensing engine may be practically doubled without the installation of additional boilers by turning exhaust steam into a low-pressure turbine connected with a condenser.

will undoubtedly come into use much more extensively with the increasing cost of fuel.

All Needs Understood

Power and heat should always be considered together in the design of any industrial power plant, and a detailed study of all the existing conditions should first be made in each case. In this investigation the whole manufacturing plant must be included, the processes examined and the needs of all departments understood before deciding upon the power of boilers and prime movers, and the best types to be used.



No power or heating plant can be operated at its highest efficiency without indicating and recording instruments which tell just what is going on in different parts of the system.

For low-pressure work such as in the case of a low-pressure turbine, water for condensing purposes must be available at low cost in order to make the arrangement an economical one. Where the supply of condensing water is limited, the water is cooled by spraying. The sprays are mounted over and discharge into a small pond, thence the cooled water is re-used.

An important detail in this connection, which is sometimes overlooked, is the varying relation between power and heating requirements at different seasons of the year.

In planning any arrangement of equipment, the entire calendar year must be taken into consideration, and provision made for operating the prime movers more economically as the use for exhaust steam diminishes.

In some cases, satisfactory results are obtained by providing an auxiliary condensing outfit for use during the non-heating season, say from the first of May to the first of October.

Best Economy in Fall

This, however, will fall short of producing the best economy in the late spring and early fall, when the relation between power and heating requirements is gradually changing. Methods of overcoming this, and automatically maintaining a true balance between the two throughout the entire year will be described in a later article.

Going on to the boiler plant, there is great flexibility, and important gains may often be made, both in economy and capacity, by means of comparatively small changes. An illustration of this is the installation of stokers for burning a cheaper grade of fuel, but one which contains practically the same quantity of heat per pound. Fuels of this kind usually require a forced draft and are uneconomical under hand stoking due to several difficulties—among them, handling, clinkering, and the large bulk of ash to be cared for.

Another important matter to which attention may be called, is that of reconstructing the furnaces for higher rates of combustion, thus increasing the boiler capacity from 50 per cent. to 100 per cent. for continuous operation and still more for temporary peak loads.

In making changes of this kind it is very important that the principles of boiler construction and operation be clearly understood, as it can only be done safely and economically under certain specific conditions.

A practice often carried on in the building up of a power plant to meet increasing requirements, is that of purchasing new pieces of equipment upon their own merit, without due regard to the plant as a whole. While these devices may do their own particular work in a satisfactory manner, they may not be the type best adapted to the conditions existing in the given plant. A good machine in the wrong place is no better than a poor one, and in many cases it may result in actual loss.

In other cases, an expensive piece of equipment may be installed for producing a small saving which is more than offset by the fixed charges upon its cost and upkeep, while some other machine included in the plant is being operated with a waste which might easily be eliminated by simple adjustments or by the substitution of a type better adapted to the existing conditions.

Questions of Labor

The questions of labor and of the uncertainty of a continuous coal supply naturally suggest the installation of coal and ash-handling equipment, and improved facilities for the storage of large quantities of fuel.

Here, as in the power house, the engineer and the owner should be familiar with certain practical matters bearing upon installations of this kind in order to secure the most satisfactory results.

If coal is stored in large quantities, care must be taken in piling it to reduce to a minimum the chances of spontaneous combustion and provision made for detecting overheating before fire actually breaks out. All of these matters will be treated in detail in future articles, as well as the selection of fuels for different operating conditions.

To Remove Soot

Accumulations of soot and ashes on one side of the plates and tubes and scale on the other, not only shorten the life of the boiler but retard heat transmission and cause waste of fuel. In order to avoid this loss, soot blowers must be provided and the feed water purified before delivery to the boilers, both of which call for practical information on the part of those in charge.

No power and heating plant can be operated at its highest efficiency without indicating and recording instruments which tell just what is going on in different parts of the system. Steam flow meters show at once when one of the units in the boiler plant fails to do its share of the work, and CO_2 indicators and recorders enable the fireman to handle his furnaces to the best advantage and the engineer to know just what is being done in this regard at all times, thus tending to insure the best methods of hand firing and the proper adjustment of mechanical stokers.

Water meters serve as a check on wastes through leaks or carelessness and give results which are useful in checking up with the steam production. Heat wasted up the chimney is indicated by means of a pyrometer, and the strength of draft by devices constructed for this particular purpose.

Recording instruments are essential to the efficient operation of any power plant and are of great assistance in the detection of wastes of various kinds.

Enough has been said to show the importance of the power plant in its relation to the main factory, and future articles will give practical suggestions and information which should be of assistance in planning new work and improving conditions in inefficient plants already installed.

Choosing the Proper Type of Electric Motor

By C. N. JOHNSON*

Study of Intended Application Must be Made by the Engineer Before Open, Semi-Enclosed, or Enclosed Units Are Selected For the Job on Hand

FROM the standpoint of ventilation, motors may be classified as open, semi-closed, totally enclosed, and enclosed ventilated. The first is the standard motor with which we are familiar. Semi-enclosing covers are sometimes added to give mechanical protection to the motor winding, to keep out all but fine dirt or other matter and to protect operatives from possible injury where the motor is located on the machine near the floor. The totally enclosed and enclosed ventilated motors serve two main purposes. Where dust, fumes or moisture, injurious to the windings is present, the enclosing feature protects the motor.

Where gases, dust or other inflammable material are present, any fire in the motor generally will be confined to the motor, except in case of a self-ventilated motor where the air discharges directly into the room.

A study of the design, installation, and general reasons for using enclosed motors brings up a number of interesting considerations. In the design we must keep within certain prescribed limits of construction and the installation of enclosed ventilated motors must be made in such a manner that the motor may function properly within the limits for which it was designed. In the application of these more expensive types of motors, we must see that common sense is applied rather than hasty judgment.

Determine Limiting Rating

The limiting rating of any motor is determined by the amount of heat which can be dissipated from the motor and still maintain all parts at a given specified temperature. In the open motor, air circulates over the windings and iron parts and helps to dissipate the heat from these parts.

Where no ventilation is provided, the enclosed motor must depend entirely for cooling on the heat dissipated by radiation and convection from the external surface of the motor. It has been found that from 2 to 2.5 square inches of motor surface are required for each watt loss in the motor to maintain a temperature rise of 55 degrees Cent. for continuous service. The heat to be dissipated is of course a function of the efficiency of the motor and the motor rating.

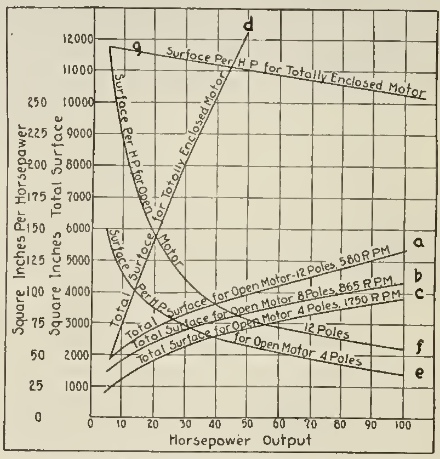
For the smaller motor ratings the external surface of the frame is comparatively large and little change is made in the rating by making the motor totally enclosed. The surface per horsepower decreases rapidly with increase in motor rating so that there is a point beyond which it is not economical to go in totally enclosed motors.

Curves Show Difference

The curves in the accompanying chart show graphically the relation between available surface for dissipating heat in open and enclosed type motors for different motor ratings. Curves *a*, *b*, and *c* show the external surface of standard open motors for different speeds and horsepower. It will be noted that the external surface for a given horsepower rating is considerably larger on a twelve-pole motor at 580 revolutions per minute than it is on the four pole motor at 1,750 revolutions per minute. The slow speed motor, therefore, lends itself more readily to enclosing.

Curve *d* shows the external surface required for totally enclosed motors for practically all speeds.

By a comparison of the curves for the open and totally enclosed motors it can be seen readily that the total surface required for enclosed motors rises so rapidly that beyond a certain rating it is not desirable or economical to build the enclosed motor. To afford a better means of determining the cause of the diversion of the above curves, curves *e*, *f*, and *g* are given to show the square inches of surface per horsepower for different ratings. Curve *g* for the totally enclosed motor would be parallel to the lower axis, except for the slight increase in efficiency as the horsepower increases. Curves *e* and *f* for the open motor fall off rapidly as the horsepower increases.



CURVES SHOWING GRAPHICALLY THE RELATIONSHIP BETWEEN AVAILABLE SURFACE FOR DISSIPATING HEAT IN OPEN AND ENCLOSED MOTORS FOR DIFFERENT RATINGS

Increasing Surface

It is possible to reduce the physical size of the totally enclosed motor by increasing its heat dissipating surface by the aid of numerous projections or ribs on the frame and brackets. Such a special frame would greatly increase the cost of manufacture and would tend to make the motor awkward for handling.

The field of the totally enclosed motor therefore, is limited to the smaller ratings, preferably below 25 horsepower.

When the enclosed feature is required on the larger ratings it is necessary to go to the ventilated type of motor. This motor is completely enclosed with the exception of an air inlet and outlet arranged for pipe attachments. Clean air is piped from an available source to the inlet of the motor, passed through the motor and exhausted into the outlet pipe which carries it again to the outside atmosphere.

In the self-ventilated type of enclosed motor the air is passed through the motor and piping by means of a blower mounted within the motor on the revolving member. In the forced-ventilated type the air is passed through the motor and piping by means of an external blower driven either by a separate motor or mechanically from the motor itself.

The ventilated type of motor when supplied with the proper amount of air affords the same conditions for taking care of the losses in the motor as obtained in the open type, so that the same size motor frame can be used as for the open motor.

It is of particular importance to see that the air supplied is pure and volume is maintained to keep the proper motor temperature. This means that the ventilating system must be considered as a vital unit of the power equipment.

Care in Piping of Air

Careful consideration must be given to piping of the air to and from the motor. The blower and piping should be of ample size. The volume of air required and the friction loss in the motor may be obtained from the motor builder.

It is advantageous to furnish the motor manufacturer with as complete data as possible as to the conditions under which the motor is to be used, an idea of the distance which air will have to be piped; information as to the temperature of the air surrounding the motor, as well as temperature of the incoming air. Often it is possible to ventilate several motors in an installation from one source of air supply.

As an example of the power required to supply ventilating air, it will be of interest to note that in tests on a 100-horsepower motor 170 watts was required to drive the blower supplying the ventilating air, which is about 0.25 per cent. of output of the motor. This will be increased where air has to be brought any considerable distance through pipes.

Limitations in Use

The writer wishes to call particular attention to the self-ventilated motor and the limitations of its use. Here the comparative ratings of the self-ventilating motor to the open motor, on a given frame, will depend entirely on the amount of air which the blowers provided on the motor will handle through the necessary piping. The space inside the motor for mounting the blower is limited.

---

*The author is associated with the General Engineering Department, Westinghouse Electric & Mfg. Co.

The higher the speed of the motor the more will be the capacity of the internal blower. Good engineering practice limits the use of motors for self-ventilation to speeds above 700 revolutions per minute so located that the total length of piping for inlets and outlets combined shall not be more than 25 feet and these pipes to be of sufficient size that the air velocity in the inlet pipe will not exceed 1,000 feet per minute.

From the foregoing it will be seen that the manufacture and installation of enclosed motors, both totally enclosed and enclosed ventilated present no serious problem.

Cost Is Higher

The important problem is the solution of the question as to when the use of the enclosed motor is justified. Naturally the cost of the enclosed motor is higher per horsepower than the open motor.

For the totally enclosed motor the physical size increases rapidly and we would expect the cost of the motor to follow closely with the physical dimensions. The totally enclosed motor can be installed as readily as the open motor and the only additional point to be remembered in this connection is the fact that the totally enclosed motor is special and is not ordinarily carried in stock so that longer shipments are required.

The totally enclosed motor is not interchangeable physically with the same rating open motor and this must also be taken into account on individually driven equipment.

The enclosed motor for forced ventilating will have a first cost of from 5 to 10 per cent. above the cost of the same rating open motor. The cost of the self-ventilated motor will depend entirely upon the conditions of application.

Blower Equipment

In the cost of the forced-ventilated enclosed motor there must be considered the cost of the blower equipment and the piping for carrying the air to and from the motor. It must be remembered also that this additional blower and piping equipment must be kept up as a part of the power system and charged to power maintenance.

The installation of the necessary piping brings in further considerations which must be kept in mind. Where cold outside air is brought through the pipes into the room, moisture will collect on the air pipes. This is often taken care of by controlling the temperature of the incoming air in some manner. Often the space into which the motor equipment is placed is limited and there is no convenient place for installing the air piping.

It has been found advantageous in most industries to divide the power supply into smaller electrical units replacing the larger sizes of former years. This has resulted in the general use of motors on individual machines, all of which has been economically advantageous to the various industries.

We must be careful, therefore, in any changes which we make in the motor equipment, that we do not unnecessarily increase the cost of installation and maintenance of these small motor units to the point that we lose the advantage which they have given us.

Protection of Motor

In the case of squirrel cage induction motors where protection of the motor is contemplated in the presence of inflammable dust or other material we should not pass hasty judgment that enclosing is the only solution of the protection problem.

With proper supervision and cleaning the squirrel cage induction motor could hardly be classed as a fire risk in most applications; for example, in woodworking plants.

A striking illustration of the change in attitude of those interested in the operation of motor drives in a large industry is that in the textile industry. When it was first suggested that individual motors be located on the various machines in the cotton mills, there was considerable agitation looking toward the total enclosing of these motors.

This was due to the possibility of setting fire to the lint from the cotton which gathered on all of the machines, and which would constitute a fire risk. The motor manufacturer contended that with proper attention, making sure that bearings were kept in proper shape and that material was not allowed to accumulate unnecessarily around the motors, there was no appreciable danger from fire.

The education of the mill men to this viewpoint has proven the manufacturer's contention and the agitation for enclosed motors has disappeared entirely.

C. A. S. E. Notes

F. S. Rutherford, honorary chairman, educational committee, C. A. S. E., in an appeal to members, asks all stationary engineers to avail themselves of the opportunities the organization offers for increasing their knowledge of engineering matters.

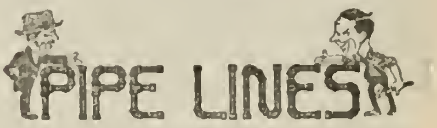
"The time is now ripe," says Mr. Rutherford, "for the local educational committee to launch a program which will induce every member of the organization to take some further training which will increase his effectiveness as an engineer.

"In many towns and cities throughout the province evening classes have been established, maintained by public funds, for the purpose of assisting employed adults to secure further training in their chosen callings. Many places have regular classes for preparing men for examinations of the Board of Stationary and Hoisting Engineers."

In towns and cities where these classes are not being conducted, Mr. Rutherford urges the local C. A. S. E. to secure the names of those desirous of taking the training, and to submit the names to the principal of the school, requesting the starting of evening classes.

Where no evening classes are being held, the C. A. S. E. should conduct the educational program, giving some time to mathematics.

A definite plan should be adopted for the coming winter months, and as many as possible should avail themselves of every opportunity through the evening classes in the technical schools, the C. A. S. E., or other suitable classes.



PIPE LINES

UNCOVERED IN ANY OLD SPOT

The power factor is always less than one except when the current is in phase with the electromotive force. Under this condition the kilovolt-amperes and the kilowatts are equal; such a condition is referred to as unity power factor.

* * *

Lives of great men oft remind us
What a lot we owe our wives;
Little women get behind us
And make something of our lives.

* * *

The effect of induction on an alternating-current circuit is to cause the current to lag behind the electromotive force, while the effect of capacity is to cause the current to lead the electromotive force.

* * *

A fireman in far off Pawtucket,
Kept all his cash in a bucket;
His daughter Nan
Ran away with a man—
As for the cash—Nantucket.

* * *

A voltmeter or ammeter when connected in an alternating-current circuit reads the mean effective value of the voltage or the current, and not the maximum value.

* * *

There was a young man from Y——,
Whose dad made his money on P——,
He went to B. C.
Got married, by gee,
And now they're expecting the St——.

* * *

It is general practice to rate all alternating-current generators synchronous motors, synchronous condensers and transformers in kilovolt-amperes instead of kilowatts.

* * *

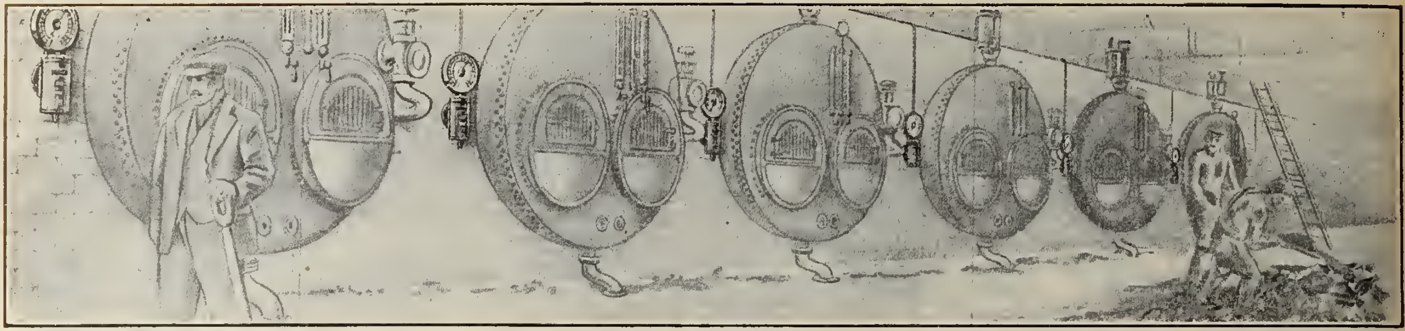
I always long for peace,
But the wheel that does the squeaking
Is the one that gets the grease.

* * *

The pull-out torque of an induction motor is the maximum torque that will develop at normal volts after being allowed to run up to normal speed, that is, the maximum torque the motor will develop when loaded to a point where it stalls. The pull-out torque is from 2 to 3.5 times the full-load torque, depending upon the design of the motor.



Easy Engineering Lessons in the Power House

By M. BARRY WATSON, B.A.Sc., M.E.
Director of Engineering, Central Technical School, Toronto.

FREQUENCY OF FIRING

IF THIN fires are to be maintained, only a little coal can be fired at a time. This, combined with a high rate of combustion, necessitates firing at quite frequent intervals. However, as this reduces the total amount of coal and ashes to be handled, the fireman's work is less than if heavier firings were made at less frequent intervals.

With ordinary draft two to two-and-a-half pounds of coal at a time on each square foot of grate surface is a good average firing. Thus on a grate five feet wide and six feet deep, about sixty to seventy-five pounds, or three to four shovelfuls, would be sufficient.

For best efficiency, the intervals between firings should average about five minutes, or may be shortened to three minutes for heavy loads if the draft is good. This gives from twenty to fifty pounds of coal per square foot of grate per hour, which is a good average. In no case should the intervals exceed ten minutes if the fires are to be kept clean and ready for heavy loads.

Minimum of Smoke

To keep the conditions of fire and draft as nearly constant as possible, and thus get the maximum of efficiency with the minimum of smoke, it will be found best to fire only one half of the fire at a time. This of course makes the firing twice as often, but is more than made up for by the coal and the labor of shovelling it which can be saved by this method.

This is known as the Alternate Method of Firing.

Slack coal is much harder to fire than coarse lumpy coal. It generally tends to "cake" or fuse into a hard tight crust. Very little air will get through this crust and the rate of combustion will be very low, thus cutting down the capacity of the boiler.

Some firemen like to place a fairly thick layer of this coal on one side of the fire. While this layer is fusing into a crust, the other side of the fire has to carry the load. After the crust has formed they break it by shoving the slice bar under it and raising the coal. The crust breaks of its own weight and the air passes through the cracks, allowing combustion to proceed at a high rate.

This method is all right with coals of which the ashes will not melt easily, but the majority of coals have an ash which melts at a comparatively low temperature, and in the use of the slice bar part of this ash is brought up into the hottest part of the fire, where it melts into troublesome clinkers.

Whether it is installing a boiler, calibrating a meter, testing a motor or any one of the many other routine tasks of power plant operation, the one best way of doing the work should be studied by the individual engineer and, modified by local conditions, adopted as his practice. Power House editors are continually seeking the one best way of doing work that they may record the results in the pages of the newspaper. They talk to engineers, study the relative merits of existing methods used, and then record in the printed page thorough descriptions of the best practices.

A good method of firing slack coal is to feed it in quite thin layers. The crust forms quite quickly and is thin enough to be broken by means of the prongs of the rake, thus letting the air through without disturbing the ash.

Another good method favored by many is known as the "Coking Method" of firing, in which the fresh fuel is placed on the dead plate where the radiant heat from the fire and the ignition arch fuses it, drives off the combustible gases and smoke which burn while passing over the hottest part of the fire, and changes the coal into coke. The coke can then be broken and spread over the fire with the hoe or rake. The only objection to this method is that unless carefully done, the ashes are sure to be disturbed.

Cleaning Fires

Undoubtedly the best method of cleaning hand-fired grates, whether while operating or at rest, is the side to side method. Here one side of the fire is allowed to burn down while a good bed of fresh burning fuel is built up on the other side. The clinker and ash from the burnt down side of the grate is then drawn forward into a heap on the dead plate or the front end of that side of the grate, using the hoe for this purpose.

Clinkers which have fused to the side or bridge walls should be broken off with the slice bar every time the fires are cleaned, otherwise they will become so big that they will seriously obstruct the draft over part of the grate, and in the endeavor to eventually remove such clinkers, the brick work is likely to be seriously damaged.

One should not pull the ashes directly out onto the floor in front of the ash pit doors, because while working up close to the door for cleaning the grate at the bridge wall, a heap of red-hot cinders at one's feet is not comfortable. It is better to rake the ashes into a heap just inside the fire door, then, place a wheelbarrow close under the edge of the fire door and rake the heap directly into it, after which it can be moved clear of the boiler front and will cause no obstruction to the draft nor for the operations to follow.

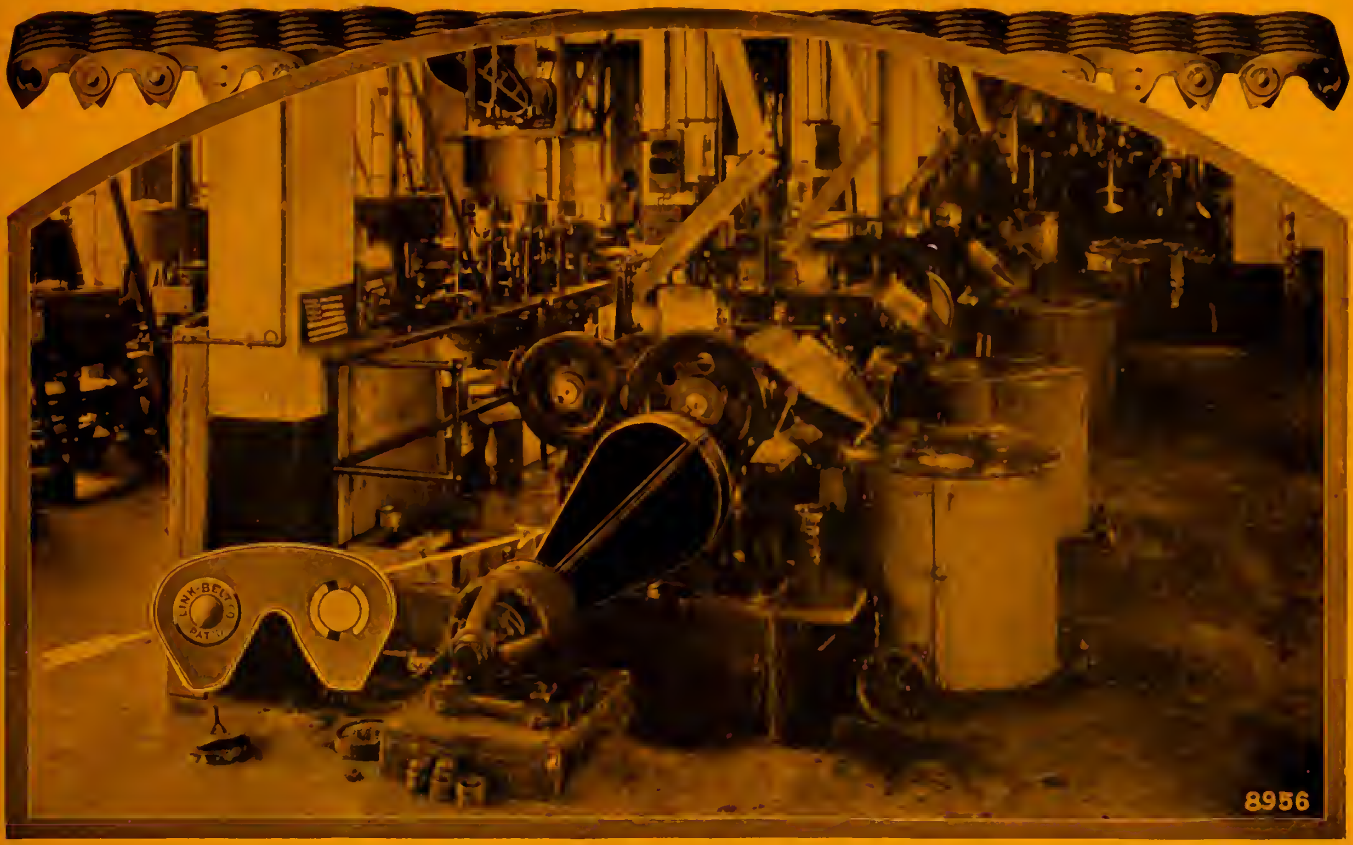
Using Slice Bar

The clean burning fuel from the other side of the grate should then be moved onto the clean grate, either by using the slice-bar with an oar-like motion or with the hoe. Care, however, must be taken not to stir up the ashes and clinkers and move them across with the clean fuel, also to see that too much of the good fuel is not left behind. The burning fuel is then spread evenly on the clean grate and covered with a good charge of fresh fuel, so there will be plenty of burning coal to cover the whole grate by the time the second half is cleaned.

After the second half of the grate is cleaned the fuel should be again spread and alternate firing carried on. The objection to the above method of cleaning grates is sometimes the inability to carry heavy loads throughout the cleaning process.

A Quick Method

A quick method of cleaning fires while carrying load is the rear to front method. In this case the clean burning fuel is pushed back against the bridge wall while the front three quarters of the grate is cleaned. It is then spread and firing is proceeded with. This method does not of



Since 1903—20 years ago—

this Link-Belt Silent Chain Drive has been operating an air compressor at the La Salle St. Station, Chicago.

This drive has required less than $5.00 repair per year. It is still good for many years economical service—even though an air compressor is a comparatively difficult thing to drive. Such is the service rendered by Link-Belt Silent Chain Drives.

Learn more about this effective, quiet drive for all kinds of machinery and lineshafting. Send for our 144 page price list data book No. 125. It is a handbook of silent chain practice. Return the coupon.

course do any good to the back part of the grate, and if carried out repeatedly, it will result in the rear part of the grate becoming completely blocked, thus cutting off about a quarter of the capacity of the boiler. Also very large clinkers will "grow" on the bridge wall, which will be almost impossible to remove without damaging the brickwork.

If such big loads are being carried that even the time necessary for a rear to front cleaning is not available, and if the burning of the coal becomes so slow on account of dirty grates that something must be done in order to continue carrying the load, the next best remedy is to run the slice bar under the fire at intervals of about one foot apart and raise it slightly. This is sufficient to shake some of the loose ash through the grates and it cracks the larger clinkers so that air can pass through them. Care must be taken, however, not to raise the bar high enough to mix ashes with the hot part of the fire, or clinkering will continue faster than ever and conditions will soon be worse instead of better.

All the above remarks apply to the cleaning of stationary grates, and the procedure detailed is much simplified in the case of shaking or dumping grates. Even with these, however, great care must be exercised, and work with the slice bar must be done in keeping the side and bridge walls clear of clinkers. There are now on the market several types of carborundum brick to which clinkers will not stick. These although very high priced are excellent for the first few rows above the grates where the clinkers form.

Banking Fires

Many engineers have a habit of banking fires at the back of the grate, either at one end of, or completely across, the bridge wall. It will be found that banking on the front part of the grate near one of the fire doors is more advantageous for the following reasons:

When the fires are again required the back part of the grate and the bridge wall can be thoroughly cleaned before the bank is uncovered, which is much more comfortable than working through a heap of red-hot cinders.

After the dead part of the grate is thoroughly clean, the bank can be spread and the hot ashes under it removed while standing well back from the fire doors. Also if large clinkers form in the bank, as they do with some kinds of coal, it is much easier to release these clinkers from the front part of the grate and the side wall, than from the rear part of the grate and the bridge wall.

Of course slack coal, if available, should always be used for banking, as lumps will burn away too fast. However, if nothing is available but lumps, these should be broken up as small as convenient and a thin layer of ashes may be placed over the bank. Although a layer of ashes tends to form clinkers, it will keep the rate of combustion within reasonable limits. With banked fires the smoke flue damper should be almost completely closed. If the damper is a good fit and closes tightly, there should be no need of closing the ash pit doors at any time as a check on the draft.

In fact it would almost be a general advantage if boiler fronts were made without closing doors. Some engineers remove the ash pit doors from the boiler fronts so that the fireman will not be tempted to use them as a means of controlling the combustion. Naturally the ash pit should be kept clean at all times, for if it is allowed to become heaped up with ashes the draft is interfered with, grate bars may be burned, and clinkers are formed. When fuel tends to clinker badly, water in the ash pit is a help.

Summary of Hints

The foregoing lesson on Hand Firing, in which an attempt has been made to show the reasons for the various points brought out, may be summarized in the following short rules:

Keep the fires between four and eight inches thick.
Fire alternate sides, lightly and often.
Do not fire lumps of coal bigger than the fist.
Keep the fuel bed level by placing coal on the thin spots, not by raking.
Do not use the fire tools more than absolutely necessary.
Keep both the fire and the ash pit clean at all times.
Control the draft by the damper, not by the ash pit doors.

Power Notes

N. Hughson, relief engineer, at Ralph, Clarke, Stone, Ltd., praises the work of the stokers in his plant.

"As our load is purely heating, the variations in steam demand throughout the day are slight. All I have to do," Mr. Hughson said this week, "is to set my stokers in the morning, and possibly make a slight change later on in the day; of course the hopper has to be kept full of coal. I have not made any adjustments since morning and you can judge for yourself if any is needed now."

The fires were certainly clean and in good order, with the steam pressure and the water where they should be.

In telling how he kept the boilers clean inside and out, Mr. Hughson mentioned that, in his opinion, a spare boiler was the greatest aid, allowing sufficient time for a thorough and proper cleaning at the correct time and not, as is sometimes the custom, only when the fires can be drawn on week ends.

"We clean our boilers thoroughly once every six weeks," said Mr. Hughson. "Soot blowers are a great labor saver and fuel saver in our plant. We have not punched a tube in three years, and they are always cleaner than they would be even after spending hours by the old methods, to say nothing of the saving in cleanliness over the old methods."

T. H. Hope, engineer at the Phillips Mfg. Co. Toronto, in relating incidents in his long career in power plants, most of which was spent in the service of his present employers, recalled a discussion he once heard between two firemen in regard to the use of the small holes in the fire door, one claiming that the sole purpose was to enable the firemen to see the condition of the fire, the other that it served the dual purpose of admitting a slight amount of air over the fire, tending to prevent smoke and also helping to keep the fire-door reasonably cool.

"Our power plant is rather unique," said Mr. Hope. "In the summer, when no heat is required for the buildings, we buy our power from the Hydro-Electric, but in the winter power is furnished by a 250-h.p. Corliss engine, the exhaust steam being used to heat the buildings and the dry kilns. The normal load on the engine is in the neighborhood of 100 h.p., so our engine is not as economical as it might be."

Some time ago, a large feed-water heater in this plant was changed over to an oil separator. The old feed-water heater was a large cylindrical tank about 4 ft. 8 in. in diameter and about 8 ft. long, fitted with 12 troughs. It did not do the work it was intended to do, and as conditions in the plant changed so that the returns came back fairly hot, it was decided to instal a small heater and to make an oil separator out of the old heater. Four vertical baffles were fastened inside the cylinder.

"Since making the change," said Mr. Hope, "we have had practically no condensate in the exhaust steam lines, and not a trace of oil in the returns."

Harry M. Prudham, engineer in charge of the power plant of the Durant Motors of Canada, Leaside, believes the fuel situation this year is not as serious as at first expected. His firm is having no difficulty in getting plenty of coal, although at times the quality is not of the best.

"Our load is fairly constant, throughout the day," said Mr. Prudham yesterday, "and our boiler capacity is able to meet the demand, but sometimes with poor coal it means hard work cleaning and attending to the fires."

Obituary

Robert Mason Kerr, president of the Kerr Engine Company, died at his home in Walkerville, on Oct. 4. Mr. Kerr was born at Leidburn, Scotland, on July 6, 1842, and first came to Canada in 1863. With his brother he went into the foundry and machine business, in which he has been actively engaged for more than fifty years. A member of Rose Lodge, A. F. & A. M., of Windsor; a councillor and former mayor of Walkerville, Mr. Kerr will be greatly missed by a wide circle of friends.

An overhead travelling crane of 25 tons capacity, with 5-ton auxiliary, is being installed in the Winnipeg city power plant by John T. Hepburn, Ltd., Toronto. This crane has a span of 33 ft. 4 in.

Electricity in the Power House

By J. A. BURNETT, M.E.I.C., Consulting Engineer, 205 St. James St., Montreal.

CARE OF TRANSFORMERS

THE transformer, usually oil insulated and either self cooled or water cooled, is a very plain and rugged appliance. However, the designers and manufacturers have devoted considerable pains to this device and many things need to be considered by the owner.

The enemies of the transformers are moisture and overload. Moisture is insidious and must be guarded against by a test every six months; while overload can be averted by general supervision, as it is indicated by undue temperature rise. The amount of temperature rise permissible is usually 40 deg. Cent. (104 deg. Fahr.) This means that with a room temperature of 25 deg. Cent. (77 deg. Fahr.) the transformer temperature must not exceed 65 deg. Cent. (149 deg. Fahr.)

Radiates Heat

The oil and casing will radiate away considerable heat, and the amount of oil is naturally a factor, i.e., a large quantity of oil and large case will mean a cooler transformer with the same load. Many transformers are provided with water cooling coils. These add about 70% to the rating of the transformer. However, many conditions of location will preclude any supply of water being used, and so the majority of installations use self-cooled transformers.

It is sometimes found, after several years time, that the water coils become foul and rusted internally, especially where the transformer coils are iron. As there may be several hundred feet of pipe, usually 1¼" diameter, in the cooling coil, it is necessary to remove the coil nest bodily and cut it midway between ends with a hacksaw. A mixture of dilute muriatic acid is then poured into the half coil and after a period of not more than an hour, the contents are poured out. Several applications will be necessary to thoroughly clean out the pipes, and a weld will be necessary to reconnect the sections midway.

Watch Oil Level

As regards the other features of the transformer, it may be found that oil will siphon out by way of the entrance leads and thus the oil level may be lowered also, in case water gets into the case, the oil level will tend to rise. The oil gauge should be inspected once a week and any difference noted. A suitable thermometer should be provided on all transformers above 100 K.V.A. capacity.

The insulating oil should be tested every six months. A sample should be drawn from the top and bottom of the transformer and labelled separately. It should then be tested by a testing bureau, the test consisting of subjecting the oil to high voltage, between two half-inch spheres with an air gap of 0.15". When tested under these conditions, dry oil should not break down at less than 30,000 volts. In practice the oil will fail at 30 to 40,000 volts.

The corrugated metal case for transformers is not so popular as formerly, as it may not be oil tight at bottoms where imbedded in the cast iron base. Boiler plate tanks are now more in use, and with good riveting, they should be perfectly oil tight.

Authorities agree that at least fifteen per cent. of the money spent in generating power and heat for Canadian industry is wasted.

It is wasted in neglected equipment, and as a result of almost unbelievable indifference to the economy of scientific combustion and the enormous waste of old-fashioned hand-fired furnaces.

Is management blind to the fact that power cost in the average plant is one of the largest single items of operating costs?

Clears All Phases

As regards protection, the oil switch with current transformer overload trip is the ideal arrangement. In case of severe overload or a short circuit, the circuit is instantly opened and all phases are clear. The objection to fuses is that, under the National Code Rating they are marked for 80 per cent. of the current at which they flow. On this basis a 30 ampere fuse would blow at 38 amperes, but they do not protect the transformers from being roasted by continuous overload and in case one fuse should blow, the motors and the transformer left on one phase would be endangered. (This, of course, refers to three phase operation.) In case fuses are used, as in the smaller sizes of transformers, it is well to make use of the oil immersed cutout. These are rather expensive, however, costing about $27.00 each. They are safe and reliable, but, of course, may open only one phase with consequent troubles.

The transformer cases should be grounded and the connection for alternation current systems must be made at each service or near the transformer, either by direct ground connection through water piping system or artificial ground wire to which are connected the grounded conductors of secondary mains. In single phase, three wire systems, the ground must be on the neutral conductor, and in single phase, two wire systems, the ground may be on either of the conductors. The ground wire should be copper without joint or splice and protected from mechanical injury. The size of the wire must not be less than one fifth the current capacity of the wire to which it is attached except that it need not be larger than No. 0 B.S. gauge.

Locate Grounds

Artificial grounds should be located where practicable below permanent moisture level. Each ground must present not less than 4 square feet surface to exterior soil. Areas where ground water level is close to the surface should be used when available.

Where ground plates are used they should be at least No. 16 stubbs gauge copper; when driven pipes are used they should be of galvanized iron and not smaller than one inch internal diameter.

The underwriters require that where large transformers are installed in a group, an oil curb be provided three inches high to prevent the oil from spreading, in case the transformer case leaks oil. This curb is set along the floor and is usually of concrete. The doors of the transformer house are required to be metal covered. In case the bank of transformers aggregate 500 Kw. total capacity, it is well to lay out the interior so that all busbars are overhead. In case the transformers are removed the busbars will not need to be touched or disconnected. The house should be well ventilated. Means should be provided to admit air freely at the bottom and to permit air to leave house at top. Roof openings are very desirable in this connection.

In case of the burnout of a transformer, it is to be noted that the salvage value is not usually over 20% of new. This is due to the fact that to dismantle the transformer and tear down the laminations, rewind the coils and re-stack the plates, assemble and test, is a very laborious operation. It therefore behooves the user of transformers to give them due care, bearing in mind that "prevention of trouble" is the motto.

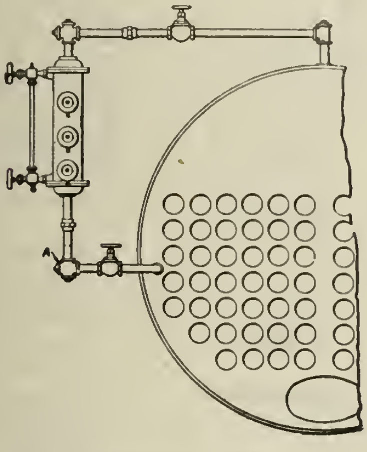
Practical Ideas From Practical Men

WATER-COLUMN VALVES

I am interested in the views of Canadian engineers on the use of valves in water-column connections on boilers. Of course it is impossible to make a steam plant absolutely foolproof, but men in charge of boilers usually do not close these valves unnecessarily when the boiler is in service. The wheel might be taken off the stem, but should be kept hanging in plain sight, near the valve. In no case should the stem be cut off.

Suppose a gauge-cock develops a bad leak; it might be days before the boiler could be let down, but with the valves in place and in order the column could be cut out for a short time, and the gauge-cock repaired or replaced.

I knew of a case where a gale of wind blew a heavy door from its fastenings. It lodged against the boiler front, breaking the cast-iron cross at the bottom of the water-column shown at A in the illustration. Only for the prompt closing of the valves much valuable paper stock, which happened to be piled in line with the pipe, would have been ruined.



Water-Column Valves.

In nearly 40 years' experience with boilers I have never yet seen any trouble caused by water-column valves being left closed. Neither have I had any trouble from scale collecting in the pipes, although I have used all kinds of water. If the boilers are blown down daily and washed out regularly, and inspected at frequent intervals, scale will not have time to accumulate in sufficient quantity to cause trouble before being discovered and corrected.

In one plant, where I was employed, the eighth floor was occupied by a bookbindery, the hot-water supply for which was taken off a branch pipe from the riser, without a valve being placed at the riser. One day, a split occurred in the branch pipe, and before word could be given to the engineer in the basement, many dollars' worth of books were damaged. A valve on this branch pipe would have saved its cost many times over.—PULP MILL ENGINEER.

COUNT THE EXPLOSIONS

By counting the explosions of a gasoline engine and doing a little simple figuring, it is possible to determine the efficiency of the hit and miss type of governing with surprising accuracy.

Subtract the number of explosions per minute made by the engine when it is pulling no load at all, from the number of explosions per minute when pulling a full load. Then divide the remainder by the number of explosions per minute when pulling full load and the quotient is the so-called "mechanical efficiency."

For a gasoline engine that explodes 95 times per minute when pulling full load, and 24 times per minute when pulling no load at all, the difference is 71. In other words, 71 of the explosions are utilized when pulling full load, whereas 24 of them are lost in overcoming the internal friction in the engine.

Going back to the rule, divide 71 by 95 and the quotient tells that the mechanical efficiency of the engine is a bit less than 75 per cent.—a rather low efficiency. It should be bettered, and it can be bettered by reducing to the minimum the number of explosions per minute when running unloaded.

It is difficult to attain a mechanical efficiency of 90 per cent. in a gasoline engine, which is common in steam engines, for steam engines are easier to lubricate and the heat problems encountered are not so complex.

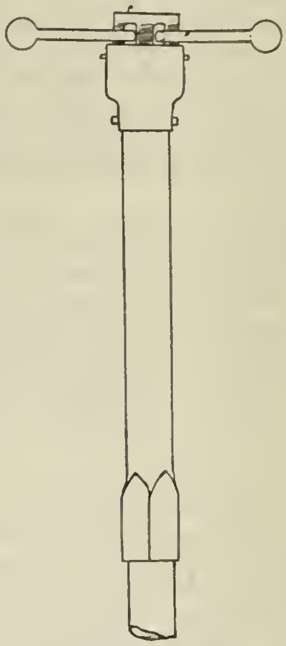
Reduction of explosions simultaneously increases the power of the engine, without consuming an ounce more of gasoline. If the number could be cut down from 24 to 10, we would have 14 "useful" explosions to add to the 71, which gives 85. Or, dividing 14 by 71, we find that the power of the engine has been increased 19.7 per cent.

It is doubtful if such an increase could be added to any engine, unless the engine were in a very sad state before the improvement began.—N. G. NEAR.

EXTENSION SHAFT

Due to a shift in our piping arrangement we found that the valve handle on one of our water supply lines came about three feet higher than could ordinarily be reached by a person on the floor. We at first placed a ladder beneath the valve but this was in the way, and usually was in some other part of the plant when it was wanted.

We, therefore, rigged up an extension shaft out of some 1½-inch pipe, along the lines shown in the attached sketch. We took one end of the pipe and put a square socket on it to fit over the original valve shaft. On the other end we put a reducing coupling, which was pinned onto the pipe, and then took a long nipple, cut five slots in it to take the original valve handle, and then screwed the nipple into place and pinned it, all as indicated on the sketch.

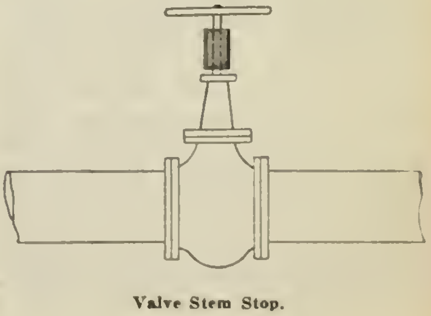


A Practical Extension.

This made a practical extension which eliminated the need for the ladder, and also saved all the red tape incident on putting through a requisition for a chain wheel or other accessory.—A. DAVIES.

VALVE CLOSING DANGER

We recently had an accident in our plant occasioned by someone completely closing the gate valve in the exhaust line beyond our open heater, with the result that the pressure accumulated, before it was noticed, to the point where it exceeded the pressure for which the apparatus was built, and the entire front section of the heater was blown out.



Valve Stem Stop.

After this was replaced, we decided to take some step against a recurrence of it, and we finally arranged to provide the rising stem of the gate valve with a collar, as shown in hatched lines on the accompanying sketch, made long enough that when the valve was closed half-way the hand-wheel was not permitted to go further down because of the distance piece formed by the collar. This half-way closed position gave us all the adjustment we needed, and the collar, which prevented any further closing, acts as a guard against anyone inadvertently closing the valve and causing a repetition of trouble from pressure accumulation.

This collar can either be made of one piece construction by sawing it from a piece of suitably sized pipe, or can be made in two parts, so that it can be readily removed. In the latter cases, in some instances it might be advisable to hold the two sections together with a padlock, where tampering is to be guarded against.—ALBERTA ENGINEER.

REDUCING VALVES

Reducing valves that are too large for the amount of steam they are to pass are usually unsatisfactory. Either they will open and close continually and chatter violently, or will stand in a position nearly closed and become steamcut and leaky. It is more satisfactory to use two small valves in parallel, one set slightly heavier than the other, so that one will supply steam up to its maximum capacity before the other opens. Another way is to use one reducing valve equal to about one-half the maximum demand, and a by-pass of about the same capacity with a hand-operated valve in it, so that when the reducing valve reaches its capacity the by-pass valve may be opened wide and the reducing valve will close down and simply make up the shortage. This, of course, required that an attendant shall observe the pressure gauge occasionally.

HOW MANY BARRELS?

Here is a chart that will be found useful for determining the number of barrels in a circular tank of almost any diameter.

Simply run a straight line across the chart connecting the height of the tank with its diameter, and the intersection with the middle column B gives the number of barrels instantly.

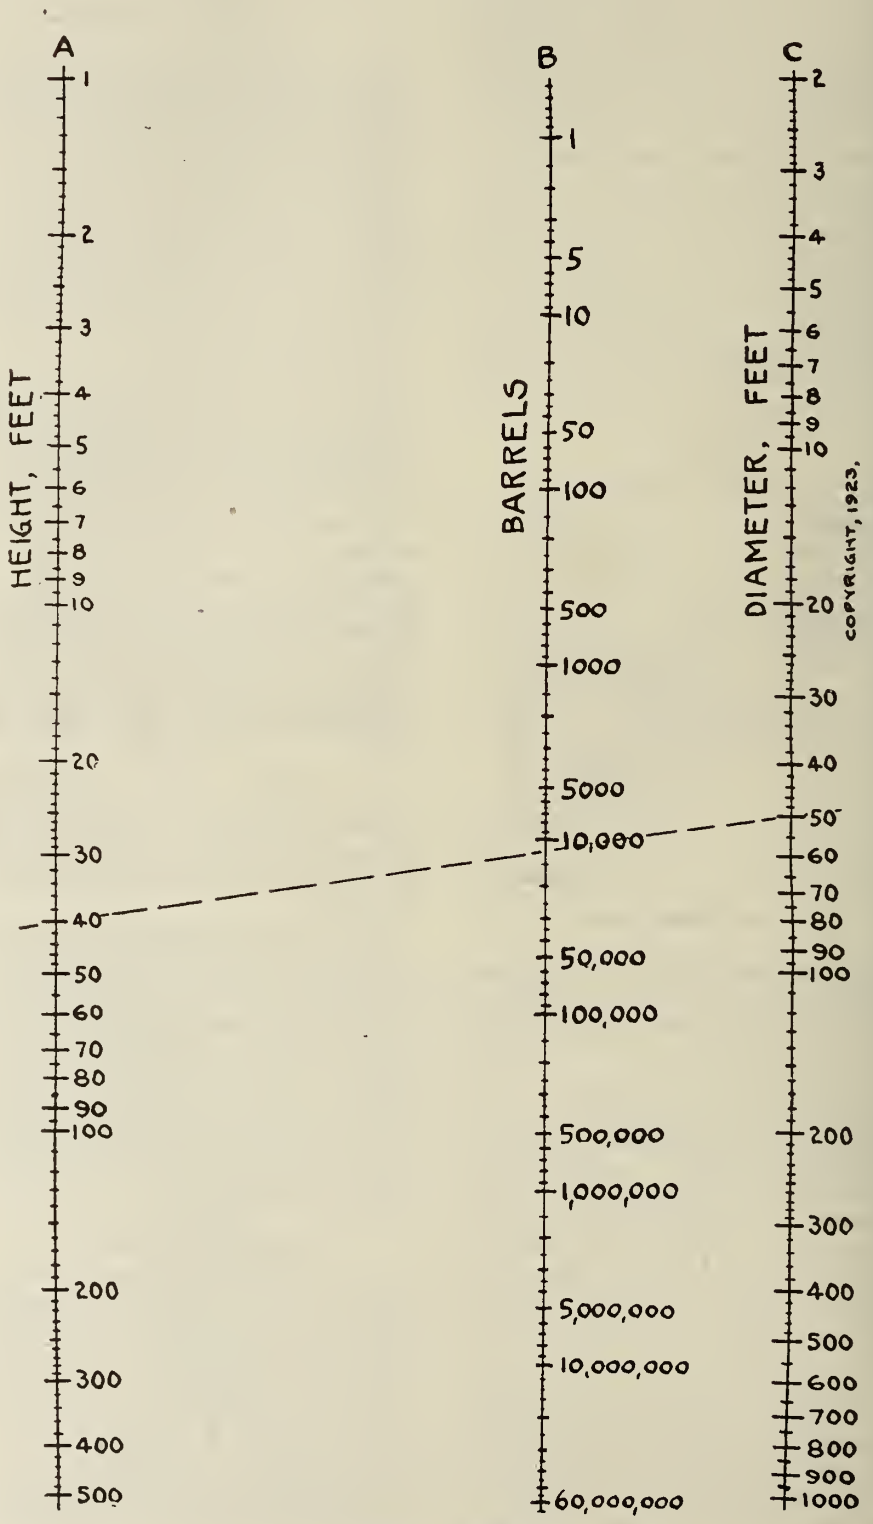
For example, if we have a tank 40 feet in height and 50 feet in diameter, what is its capacity? The dotted line drawn across the chart shows how it is done. Connect the 40, column A, with the 50 feet, column C, and the intersection with column B gives the answer as—about 12,000 barrels. Figure it out with a lead pencil and it will be found that the correct answer is 11,750 which shows that the chart gives results that are remarkably close.

In case it is desired to know how much is in a given tank at a given time, column A, represents the depth of the liquid in feet, and column C the diameter, as before. The figures in column B then represent the number of barrels in the tank.

The chart may also be used backwards for determining the height to which a given tank should be built or the diameter it should be given for a capacity of any number of barrels. Or, it may be used for determining the height to which a tank should be built where the capacity and diameter are both known. In other words, where any two of the factors are known the third is easily found by means of this chart.

The range of the chart, it will be noted, is great enough to take care of any tank ever built, the heights varying all the way from 1 foot to 500 feet and the diameters from 2 feet to 1,000 feet. The maximum capacity of the chart is 60,000,000 barrels. —W. F. SCHAPHORST, M.E.

Viscosity tests, so called, do not necessarily prove anything of the lubricating quality of an oil, since rosin or other viscous oils may constitute a large proportion of the whole and yet have no lubricating value.



How many barrels?

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

CLEANING UP AN ENGINE

What is a good method of cleaning up an engine that has stood idle for some time? —FRANK WATSON.

Answer:—Gummy deposits of oil should be softened with a paste of potash and removed by scraping with a putty knife or other flexible scraper. In places where the gum seems to be burnt into the metal, the finished surfaces can be brightened by sandpapering, being careful to do the rubbing so the marks will be in the same direction as those of the original finish.

After cleaning, the parts should be flushed clean with water, dried and oiled. The use of loose emery or of emery cloth or emery paper is objectionable as particles of the emery that may get between rubbing surfaces are likely to cause cutting that is difficult to stop.

DIRECTION OF COMPRESSOR

We have in our Montreal plant a two-stage air compressor 21 in. x 23 in.x16 in., driven 214 r.p.m. by a synchronous motor. Will this machine run as quietly "running over" as "running under"? Why are motor-driven air compressors generally run under instead of over?—F. W. RYAN.

Answer:—Quieter running of a motor-driven compressor is obtained by "running under"—that is, when the crank falls in the beginning of a stroke from the cylinder toward the crankshaft—for then the alternate thrust and pull of the connecting rod, as well as the weight of the crosshead, bring the pressure of the crosshead on the lower guide.

In a steam engine, where the power is transmitted from the crosshead to the crank, pressure is brought on the lower guide and quieter operation is obtained by "running over."

By "running under" in case of a motor-driven compressor, or "running over" in case of a steam engine, there is better opportunity for lubrication of the guide that receives the principal wear, better opportunity of adjusting and maintaining alignment of the crosshead and less tendency of the crosshead to pound on the guides.

Motor-driven compressors are run under more generally than over, so the pull of the driving belt will come on the under side of the belt and thereby better provide against slippage of the belt on the motor driving pulley.

DRAFT LOSSES

What should be the size of smoke flue for a battery of boilers containing 5,000 sq.ft. of heating surface, and what allowances should be made for loss of draft due to the length and angles in the flue?—R. SMYTH.

Answer:—A safe rule for figuring cross-sectional areas of circular iron flues is to allow 3.5 sq.ft. per 1,000 sq.ft. of boiler-heating surface, so that 5,000 sq.ft. should have a cross-section flue area of about 17.5 sq.ft., or about 56½ in. diameter.

The area at any point may be in proportion to the volume of gas that will pass that point, and when two or more branches discharge into the same duct, each junction should be provided with a baffle for turning the gases into the main flue without interfering with the passage of gases from connections that are more remote from the stack.

The retarding effect of a square flue is 12 per cent. greater than that of a circular flue of the same area, and that of a rectangular flue with sides as one to one and a half is about 15 per cent. greater than for a circular flue of the same cross-sectional area. For iron flues there is draft loss about 0.1 in. of water per 100 ft. length of flue and 0.05 in. loss for each right-angle turn. The retarding effect of brick or brick-lined flues is about one-third more.

When a turn is made by an easy-bend elbow, having a center line curved to a radius of three diameters or more, the draft loss is practically no more than for the same length of straight flue.

BOILER HORSEPOWER

What is the horsepower of a horizontal return tubular boiler, 18 ft. long, 6 feet in diameter, with 72 4-inch tubes?

What will the horsepower be if 15 sq. ft. of heating surface is allowed for each boiler horsepower?

—C. LEAK, Hamilton.

Ans.—To find the horsepower of a boiler, it is first necessary to find the total heating surface of the boiler, then allow a certain number of square feet of heating surface per boiler horsepower.

The total heating surface of a horizontal return tubular boiler consists of part of the shell exposed to the hot gases, the tubes and the tube sheets at each end of the boiler.

A Toronto manufacturer makes the following assumptions in calculating the horsepower of a return tubular boiler:

One-half the area of the shell is effective heating surface;

Two-thirds of one tube sheet as an average for the area of the tube sheets exposed to the hot gases.

The nominal diameter of the tube is used in finding the heating surface of the tubes.

The boiler is 18 feet long, 6 feet in diameter, and has 72 4-inch tubes.

Heating surface in the shell—

$\frac{1}{2}(\pi \times 6 \times 18) = 169.6$ sq. ft.

The numerical value of π is 3.1416.

Heating surface in tubes—

$72(\pi \times \frac{4}{12} \times 18) = 1{,}357.2$ sq. ft.

Heating surface in tube sheets—

$\frac{2}{3}(.7854 \times 6 \times 6) = 18.8$ sq. ft.

Total heating surface = 1,545.6 sq. ft.

The heating surface is then about 1,546 sq. ft.

If we allow 10 sq. ft. of heating surface per boiler horsepower, this boiler would be 154.5 h.p.

Allowing 15 sq. ft. per boiler horsepower, a rating used commonly for heating boilers, the horsepower is 103.

The manufacturer's rating on a boiler of this size is 150 h.p.

RESULTING TEMPERATURE

What will be the resulting temperature when 100 lbs. of water at 70 deg. F. are mixed with 15 lbs. of ice at 32 deg. F.? —S. M., Edmonton.

Ans.—Let the resulting temperature be X deg. F.

Assume that no heat is lost through radiation. The heat given out by the water in cooling from 70 deg. to X deg. is used up in melting the ice and raising the water from the ice up to a temperature of X deg.

Heat given out by water in cooling from 70 deg. to X deg. = 100(70—X) B.t.u.

The latent heat of fusion for ice = 144 B.t.u. per lb.

Heat required to melt the ice =
15 × 144 = 2,160 B.t.u.

Heat required to raise the temperature of the water from the melted ice to X deg. = 15(X — 32) B.t.u.

Now, if no heat has been lost in the process of melting and exchange of heat, the heat given out by the 100 lb. of water in cooling from 70 deg. to X deg. will be equal to heat required to melt the ice and to raise the temperature of the water to X deg. F.

Equating to find X—

$100(70 - X) = 15(X - 32) + 2{,}160.$

$7.000 - 100X = 15X - 480 + 2\,160$

$7{,}000 + 480 - 2{,}160 = 100X + 15X$

$115X = 5.320.$

$X = 46.2$ deg. F.

The resulting temperature is, therefore, 46.2 deg. F.

There will be a slight error in working a problem in this way, due to the assumption that the heat content of water at 70 deg. F. is 38 B.t.u. per lb. instead of the more accurate 38.07 B.t.u.

per lb. The difference is so slight, however, that for all practical problems it is usually neglected.

SETTING VALVE

What is the proper method of setting the valves on a single cylinder, centre crank Ideal engine, equipped with a Rites inertia governor?

—A. L. COCKING, Man.

Ans.—To find if the governor is working properly, remove the spring and try out the eccentric, from the inner to the outer stop, through the total range.

When the eccentric is tight against the outer stop, the valve must show no lead. This is the safety feature of the engine. No steam must be admitted to either end of the cylinder with the eccentric tight against the outer stop, or on light or no load the engine will run away.

Replace the spring and set to the normal tension. The eccentric will now bear against the inner stop, giving the maximum travel of the valve.

Block the governor arm solid at a position giving cut-off at approximately ⅜ stroke.

If the valve is properly set, it will now show equal opening to steam at both ends of the cylinder.

If the valve opening is greater at one end of the stroke than at the other, adjust by means of the lock nuts on the valve rod until equal opening to steam is shown at both ends.

LUBRICATING CYLINDER

What is the proper amount of cylinder oil to use on 12 x 12 steam engine, speed 277 r.p.m., working on wet steam at a pressure of 100 lb. per sq. in.?

—A. L. COCKING, Dauphin, Man.

Ans.—The correct amount of oil to use on engines of the same size and speed varies, new engines requiring more than old ones. It is also difficult to secure proper lubrication with wet steam. Engine builders recommend about one pint of good cylinder oil per 24 hours as a maximum on an engine of this size.

VELOCITY OF DISCHARGE

What would be the velocity of water discharged through a 12-in. pipe inserted at the base of a dam with the head of water 25 ft.?—ROBERT HOAG.

Answer:—The average velocity would depend on the shape of the inlet end of the pipe, the length of pipe, roughness of the pipe surface and also the pressure against which the discharge takes place. The theoretical velocity in feet per second would be 8.03 times the square root of the head 25 ft., or 40.1 ft. per second. For a straight clean pipe 2½ to 3 times as long as diameter the average velocity would be about 81 per cent. of the theoretical, or 81 per cent. of 40.1 equals 32.48 ft. per second.

This provides that the pipe is uniform in diameter for its full length, that the entrance end is cut off square, that the length of the pipe is 2½ to 3 times the diameter, and that there is no obstruction of free flow to the entrance tending to reduce the head of 25 ft. at the entrance.

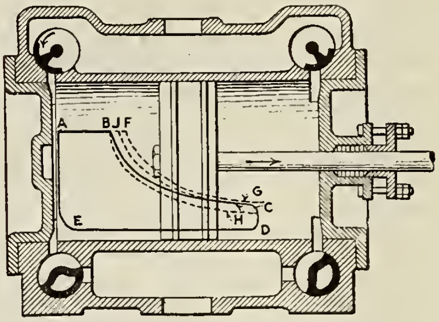
With a bell-shaped mouth at the entrance of the pipe, the velocity in a short pipe would be nearly the theoretical, and for a longer pipe than three times the diameter, the velocity and discharge would be reduced, depending on the size, length and roughness of the interior of the pipe.

CYLINDER RE-EVAPORATION

What is cylinder re-evaporation and why is its occurrence associated with poor cylinder economy?—WALTER HUDSON.

Answer:—The walls of an engine cylinder are cooled by radiation and the low temperature of the exhaust steam, and when steam is admitted from the boiler, part of it condenses.

The latent heat of that portion of the entering steam that is condensed is employed by raising the temperature of the cylinder walls nearly to the temperature corresponding to the pressure. The water formed by the process of condensation is deposited on the walls of the cylinder in the form of a thin film. This continues after cutoff takes place until the steam pressure and corresponding temperature have become reduced by expansion of the steam down to a pressure at which its temperature is about the same as the temperature of the cylinder walls.



Cylinder Re-evaporation.

Then, upon further lowering of the steam pressure from further expansion, the water in the cylinder is re-evaporated and the steam thus formed in the cylinder during the latter part of the stroke prevents the pressure from falling as low as it would without the re-evaporation. As a result the expansion line of an indicator diagram from the point where re-evaporation begins may be higher than it would be without the re-evaporation.

Referring to the figure, suppose *ABCDE* to be an actual indicator diagram with cutoff at *B*. Assuming a zero clearance volume, the volume of steam in the cylinder at cutoff is the volume displaced by the piston in movement from *A* to *B*.

But on account of cylinder condensation during admission, the actual volume of steam admitted from the boiler is greater. Suppose this additional volume to be a cylinder volume represented by the additional piston displacement from *B* to *F*. Then by adiabatic expansion—that is, with neither gain nor loss of heat excepting the heat converted into work—an expansion curve like *FG* would be realized, whose average pressure would be more than that of *BC*.

If there had been no re-evaporation to raise the average pressure after cutoff at *B*, adiabatic expansion from *B* would have proceeded along a lower curve like *BH* of less average pressure than the curve of the actual diagram; but the fact that *BC* is higher than *BH* shows that heat for re-evaporation of water in the cylinder must have been received. By passing an adiabatic *CJ* through *C*, it will be found that without gain or loss of heat an expansion curve like *JC* would have been necessary to pass through *C* and would have required a volume of steam to be admitted from the boiler at least equal to the piston displacement *A* to *J*.

But the average pressure of the actual diagram *BC* that is obtained for the quantity of steam represented by the displacement *AJ* is less than the theoretical average that should have been obtained, going to show that the work realized from re-evaporation is less than would have been developed without cylinder cooling and the incident re-evaporation.

In this connection it is to be noted that an average pressure higher than the average pressure of an adiabatic through *B*, or an average pressure lower than that of an adiabatic through *C* is indicative of a loss from cylinder cooling which is not replaced by a gain from re-evaporation.

Convention Notes

The 14th annual convention of the National Association of Practical Refrigerating Engineers will be held in Memphis, December 12, 13, 14 and 15, 1923. The convention sessions will take place in the Scottish Rites Temple on Union Ave. Plan of the exhibit space can be had from Wm. F. Davis, 630 Jackson Ave., Memphis, Tenn.

Announcements

In a recent issue of Power House there appeared an advertisement by the Celite Products Co. on Sil-O-Cel Insulation, in which the statement was made that Sil-O-Cel insulating brick possessed a crushing strength of more than 400 lbs. per sq. ft. Sil-O-Cel insulating brick possesses a much greater crushing strength and the statement should have read: "400 lbs. per sq. in., the equivalent of about 28 tons per sq. ft."

Richard & Abra, Home Bank Bldg., Ottawa, are the architects for a garage, machine shop and power house for the Ottawa Electric Railway Co. A booster generator, costing about $50,000, will be required for the power house. John Sutherland is the superintendent in charge.

The Canada Stoker Co., 2 Gould St., Toronto, have been awarded, by the department of public works of the province of Manitoba, the contract for supplying and erecting one 80 sq. ft. chain grate stoker for the new power house of the Hospital for Mental Diseases, Selkirk.

BIG CO_2 SAVINGS

(Continued from page 31)

Ultimate Analysis of Dry Coal

Carbon.....	77.00 per cent. by weight
Hydrogen...	5.00 per cent. by weight
Oxygen.....	8.00 per cent. by weight
Ash........	10.00 per cent. by weight

Dry Flue Gas Analysis

Carbon dioxide	12.00 per cent. by volume
Oxygen.......	4.50 per cent. by volume
Carbon monoxide .	1.50 per cent. by volume
Nitrogen......	82.00 per cent. by volume

The weight of the dry products of combustion per pound of dry coal is given by the equation,

$$\text{Weight dry products} = \frac{4\ CO_2\ O_2\ 700}{3(CO_2\ CO)} \times C$$

Weight of dry products =

$$\frac{4 \times 12\ 4.5\ 700}{3(12\ 1.5)} \times .77 = 14.31 \text{ pounds}$$

per pound of coal.

In order to find the theoretical weight of air required to burn one pound of fuel it will be necessary to find the weight of carbon that is burned to carbon dioxide and to carbon monoxide. The assumed flue gas analysis can be converted to per cent. by weight with the following result.

Carbon dioxide	17.51 per cent. by weight
Oxygen.......	4.78 per cent. by weight
Carbon monoxide .	1.40 per cent. by weight
Nitrogen......	76.31 per cent. by weight

Of the total weight of the dry products of combustion of one pound of dry coal, 1.4 per cent. is carbon monoxide. Therefore, the weight of carbon monoxide per pound of fuel is 14.31 × .014 = 0.2 pounds. Since carbon is 12 ÷ 28 of the weight of carbon monoxide, the weight of carbon burned to carbon monoxide is $0.2 \times \frac{12}{28} = .086$ pounds per pound of fuel The carbon burned to carbon dioxide is .77 — .086 = .684 pounds per pound of fuel. The weight of air required theoretically to burn one pound of the coal under the assumed conditions is as follows: Weight of air =

$$11.58C\ 34.8\ (H - \frac{0}{8})\ 5.78C = 11.58 \times .684\ 34.8\ (.05 - \frac{.08}{8})\ 5.78 \times .086 = 9.81$$

pounds per pound of coal.

The air actually used under the assumed conditions is the weight of the dry products of combustion minus the weight of the carbon in the fuel plus the weight of the oxygen supplied to burn the hydrogen. Hence, actual weight of air =

$$14.31 - .77\ 8(.05 - \frac{.08}{8}) = 13.86 \text{ pounds}$$

per pound of coal

The apparent excess air is 13.86 — 9.81 = 4.05 pounds.

Now, if the assumed flue gas analysis is correct for the given coal analysis, it should check with the flue gas analysis calculated from the above excess air. To calculate this flue gas analysis, per cent. by volume, the following results:

Volume of	Cubic Feet
Carbon dioxide = $.684 \times 3.67 \times 8.15 =$	20.45
Carbon monoxide = $.086 \times 2.33 \times 12.80 =$	2.57
Oxygen = $4.05 \times .23 \times 11.21 =$	10.46
Nitrogen = $13.86 \times .77 \times 12.77 =$	136.00
	169.48

Carbon dioxide $\frac{20.45}{169.48} = 12.08$ per cent. by volume.

Oxygen $= \frac{10.47}{169.48} = 6.17$ per cent. by volume.

Carbon monoxide $= \frac{2.57}{169.48} = 1.52$ per cent. by volume.

Nitrogen $= \frac{136.00}{169.48} = 80.23$ per cent. by volume.

Since this analysis does not agree with the assumed analysis, it is evident that the latter is not correct or at least it cannot be used with the given coal analysis

PROTECTING TRANSFORMERS

(Continued from page 34)

ent when lifting the transformer core and windings from the tank for inspection.

By far the greatest number of faults occur between turns of the H. T. windings, and while with modern protective gear such as described in this article, the fault becomes confined over a relatively small area, even then the resulting damage gives ample visual evidence for the purpose of location.

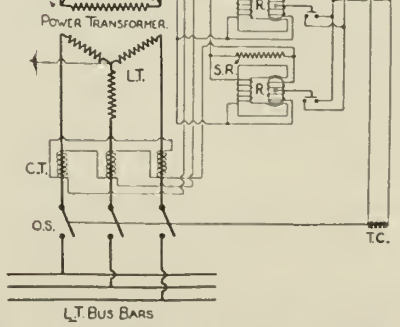


Fig. 8—McColl Circulating Current Protection, using Biased Reactive Dynamometer type relays for a three phase delta/star transformer.

The foregoing review has been confined to those types of protective gear having discriminative action, and the various kinds of overload and earth leakage protection have not been considered, as their application and characteristics are more widely known. The particular kind of protective gear to be installed will largely depend upon the importance of the continuity of supply as compared with the cost of the protective scheme, but in all cases where transformers form a link in the transmission or distribution scheme, they should certainly be protected by some form or other of the systems described in this article.

Construction

The Ottawa River Power Co., Ltd., 145 St. James St., Montreal, is in the market for transmission and power machinery to be used in connection with a proposed 60,000 h.p. scheme in Quebec.

The Sinclair Construction Co., Ltd., Excelsior Life Building, Toronto, has the general contract for the construction of a power house, foundations, and tailrace at dam No. 1, Trent River, in connection with the $250,000 development at Campbellford, Ont., for the Hydro-Electric Power Commission of Ontario, University Ave., Toronto.

Frank M. Campbell, William E. Hunt, and John L. Comfort, Fort Erie, Ont., have incorporated a company to be known as the Campbell-Aladdin Gas Maker, Ltd. Capital $250,000.

Plans are being prepared for the construction of an ice arena, 85 x 185 feet, at Niagara Falls, Ont., by the Niagara Falls Arena, Ltd. Estimated cost $150,000. The owner is in the market for an artificial ice plant. F. Barber & Associates, Ltd., 45 Jarvis St., Toronto, Engineers.

Burmeister & Wain, of Copenhagen, recently received an order for the construction of two Diesel engines, developing 1,000 H.P. per cylinder. A single cylinder engine unit has been in operation for over four months on test, including a non-stop run of about a month, which was made with very satisfactory results.

The engine is of the double-acting, four-cylinder type. The successful operation of an engine developing 1,000 H.P. per cylinder will do much to encourage other builders to make engines of large size suitable for central stations.

The Ottawa & Hull Power Co. will begin construction on their power plant at Bryson, Quebec, immediately. This plant will develop 60,000 h.p. and supply power to the communities along the Ottawa River as well as in the cities of Ottawa and Hull.

Selecting the Proper Pulley for Fans or Pumps

By A. E. HEWITT

Correct Proportioning of Sizes on Belt Driven Apparatus of Importance to Engineer—A Difference of an Inch in Diameter May Have Vital Effect on Operation

THE proper proportioning of pulley sizes on belt-driven apparatus such as fans, power pumps, etc., is very important. A difference of an inch in diameter of either pulley may have a pronounced effect on the operation of the devices, and if the error results in a pulley on the motor which is too large, the result will be an overloaded and burnt out motor sooner or later. If the proportion is the other way, the apparatus that is being driven will be operating at a lowered capacity.

In our calculations we deal so much with areas, and so little with circumferences, that in attempting to proportion pulley sizes we are apt to be misled by the fixed idea that doubling the diameter results in an area four times as great, and therefore, confuse ourselves when dealing with circumferences. Doubling the diameter of a circle increases the circumference in the same proportion, and likewise 1½ times or any other increase or decrease.

Radius Immaterial

This is illustrated graphically by the six circles in the accompanying illustration, three being 20 in. and three 10 in.; the upper 20 and 10 in. circles illustrate relative diameters only, with the radius of each marked in the circles; with radius, however, we have no concern.

The two in the centre illustrate the relative areas, which, as will be noted, are four times as great for the 20 in. as for the 10 in. The two lower circles illustrate the circumference, which, as will be seen, increases with the diameter, the circumference of the 20 in. circle is just twice that of the 10 in.

Therefore, in calculations affecting pulley sizes, circumferences, with the attendant decimal calculations, may be dispensed with and diameter only used in figuring the required sizes.

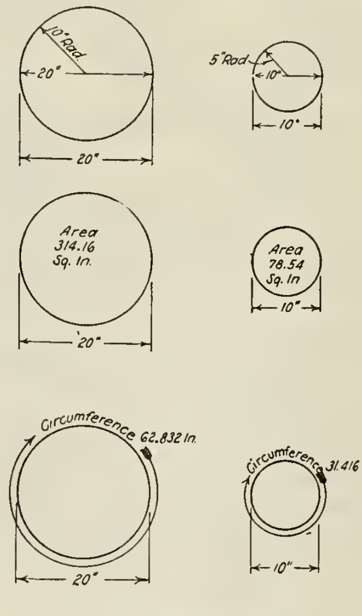
The small motors used in heating work for operating pumps, etc., are usually of 1,800 revolutions per minute, although 1,200 and even 900 are used to some extent. For operating fans 1,200 and 900, and sometimes lower, are met with more often than the 1,800 r.p.m.

Speed of Pumps

The speed of power pumps of the reciprocating type is fixed by the service, and by the length of each stroke, and is held to a given number of feet per minute travel of the piston.

Manifestly a pump with a short piston will have a greater number of revolutions per minute in order to attain the same speed as one with a longer piston. But as the length of piston increases, the speed per minute may be increased, so that the long piston will attain a higher speed with the same number of revolutions.

As an example, pump with a 6 in. stroke making 100 revolutions per minute will have a piston speed of 100 ft. per minute, while one with a 9 in. stroke would only have 66 2-3 revolutions per minute to attain the 100 ft. per minute piston speed of the smaller stroke. The proper speed is always indicated by the manufacturer.



Proper Pulley Sizes.

Speed in Fan Work

In fan work the number of revolutions per minute is related to the required tip speed of the fan, and this will of course depend on the diameter of the fan wheel. A wheel of 36 in. diameter, revolving at the rate of 300 r.p.m. will have a tip speed of 2,827 ft. p. m., while a wheel of 72 in. diameter would attain this same tip speed at 150 r. p. m.—just one-half the number of revolutions per minute.

Both fans and pumps, as well as other such devices, have a fixed number of r. p. m. recommended by the manufacturers with usually some recommendations as to percentage of variation from the given speed; ordinarily about 10 per cent. They usually also, catalog a given pulley size, which can, however, be varied. Motors also have a fixed speed, and usually a catalog size of pulley which may also be varied.

Dividing the Speed

Having a fan of a given speed and a motor of given speed, and knowing the size of pulley on the fan, the pulley size of the motor may be arrived at by dividing the motor speed by the fan speed, and then the fan pulley diameter by this quotient. Example:

Fan speed 400 r. p. m.
Motor speed 1,800 r. p. m.
Fan pulley 27 in. diameter; then:
1,800 ÷ 400 = 4.5
27 ÷ 4.5 = 6,

which is the proper diameter for motor pulley.

If the speed of both fan and motor are given, as above, and the pulley diameter of the motor is 8 in., proceed as before:

1,800 ÷ 400 = 4.5

then 4.5 × 8 = 36, which would be the proper pulley diameter for the fan with the motor pulley 8 in.

A study of the illustration will help to make this matter clearer.

Personals

The University of British Columbia is calling for tenders for the heating and ventilating of the new science building now being constructed at Point Grey. Patrick Philip is the general contractor.

The Ottawa River Power Co., a subsidiary of the Ottawa and Hull Power Co., have completed plans for development at Bryson, 50 miles above Ottawa. The first installation is to be one unit of 25,000 horse power.

E. N. Saunderson, N. Y., president of the New Brunswick Power Co., met Premier Venict at Fredericton, Oct. 5, to discuss improvements to the highway at East St. John, where the New Brunswick Power Co.'s tracks run.

The Hydro Electric Power Commission, North Bay, have purchased from the Canadian Ingersoll-Rand Company a 3¼ and 1¼ x 4 type 14, 1,000 lb. pressure air compressor for Hydro No. 2 generating station, at North Bay.

Julian C. Smith, of Montreal, president of the Quebec Light, Heat and Power Co., and supervising engineer for the Manitoba Power Co., in company with A. W. McLimont, visited the Great Falls development this month to inspect the work.

Duty of a Power Plant Engineer As I See It!

By C. J. MATHEWS, M. Inst. C. E.*

Operators Must Become as Efficient as Possible in Order to Eliminate Waste and Win Substantial Recognition of Savings Effected in Boiler Room

KEEP the water in the boiler at a uniform level; a varying water level tends to uneconomical results. Water gauges should be tested every morning before starting, or after any stoppage. They should also be frequently tested while boiler is at work. Every cock should be used at each testing. If water rises slowly in the glass, passages should be cleaned out with a piece of wire.

Pumps and feed valves should have constant attention so that there may be no risk of water shortage. Pumps should be kept going slowly all the time so as to keep the water at a uniform level.

If from any cause it is suspected that the water has become so seriously low that there is danger of furnace crown plates being bared, close dampers and smother fire with sand, damp ashes, earth, or even slack. Ascertain, if possible, the exact water level, and if furnace plates are not bared, turn on feed until the normal water level is restored. If it is almost certain that plates are bared, and have become overheated, draw fires after they have been completely smothered, and allow boiler to cool before turning on feed.

Renew Yearly

Fusible plugs must be kept clean from soot on fire side and scale on water side. The fusible metal should be renewed if at any time it appears to be getting brittle when scraped with a knife. It is generally good practice to renew the metal yearly.

See that all fittings are kept in good and efficient working order. Care should be taken to see that blow off cocks are properly closed after using them, and are not leaking. All fittings should be taken apart and thoroughly overhauled twice a year, when connecting bolts, studs, etc., should be carefully examined and renewed if corroded or otherwise defective.

Manhole and mudhole joints should be kept scrupulously tight. Very slight leakages from these doors can cause serious corrosion of the surrounding plates.

The interior of all boilers should be kept as free from scale and deposit as possible, and the plates in external flues and flue tubes kept free from soot. A dirty boiler is a wasteful boiler, and is always more difficult to fire than a clean one.

Clean Thoroughly

It is important that cleaning should be very thorough when preparing a boiler for inspection. It is impossible to detect defects through thick scale or a layer of soot. The principal fittings, such as safety valves, should, if required, be taken to pieces for inspection, and should be thoroughly overhauled, when found necessary, before restarting the boiler.

The boiler should not be emptied under steam pressure. Whenever possible the water should be allowed to remain in the boiler till everything, including the brickwork setting, is cool. This prevents the comparatively soft scale being baked hard on the plate and makes it much more easily removable.

Never close a boiler until satisfied that no bags, tools, etc., are left in it, and always see that all openings such as blow off, safety valve, stop valve, check valve, and passages to glass water gauges are clear.

When once the safety valves have been properly adjusted to relieve at the authorized working pressure, no extra weights must be hung on levers, nor must a direct spring loaded valve be screwed down. If the valve leaks it should be ground in or otherwise repaired.

Avoid Holes in Fire

The fuel should be evenly spread, special care being taken to avoid "holes in the fire," i.e., bare patches of grate bars. Any cracks in the brickwork or other casing material should be luted up with fireclay or otherwise stopped. Such cracks allow cold air to enter, and tend to destroy the draught and greatly interfere with economical firing. Larger charges of fuel are not so effective as smaller quantities introduced more frequently.

Grate-bars should be kept clear of clinkers or they will quickly burn out. The clinker also prevents proper supply of air to that part of the grate it forms on. Every engineer should remember that his fuel bill runs into thousands of dollars a year, and that careless stoking may increase the amount very considerably, and is perfectly certain to throw a lot of extra work on himself.

The actual firing should be done as rapidly as possible, and of course judiciously, and the firedoor kept open for the shortest possible periods.

Use Damper

Fires should be regulated by the damper, and not by opening the firedoor. Dense smoke is always a sign of uneconomical firing. Entire absence of smoke may, on the other hand, mean that too much air is being admitted through the grids in doors. The best results with the least labor are obtained when the boiler is discharging a light smoke.

Most fuels require some extra air through the grids after firing. This, however, should be reduced as soon as the fresh charge is properly alight.

Grease of any kind should be carefully excluded from boilers. Serious overheating of furnace plates is likely to occur if even a very little grease finds its way into the boiler.

The proper place to treat feed water is before it enters the boiler, but if there be no means of doing this, great care should be used in the choice of a boiler compound. Where feed water is very sedimentary or corrosive, efforts should be made to procure a purer supply, or, failing this, the water should be analyzed, with a view of finding the best way of treating it. Generally speaking it is quite safe to introduce a few handfuls of common washing soda (or a lesser quantity of soda ash) per day, with a view of softening the scale and neutralizing any acidity in the water. The effect of any given quantity should be noted and the supply regulated accordingly.

Drain Water

Opening steam valves should be done carefully, otherwise serious damage may occur through "water hammer." All drain cocks on cylinders and any drain cocks on low-lying parts of the steam pipes or at stop valves should be opened, and when all water has ceased running from them the stop valve on the boiler may be slowly opened a little, gradually increasing the opening as cylinders and pipes become warm enough to prevent excessive condensation.

If a stop valve is suddenly opened to a range of pipes containing a lot of condensed water, a series of violent explosive knocks is heard, and these frequently result in the destruction of joints and sometimes split the pipes.

All steam pipe lines should be efficiently drained, and it should be remembered that "steam traps," though quite efficient for this purpose when pipes are in use and full of steam, are entirely inoperative when the pipes are closed and have a lot of water in them.

A boiler operator has many opportunities to either waste or save considerable sums in the course of a year for his employer, and it should be his aim to take an intelligent interest in his work and become as efficient as possible, and having done so he will find that his work is less arduous than if he performed in a careless or indifferent manner, and in addition to this, his services will be fully appreciated.

---

*Chief Inspector of Power Plant Operation, Western Australia.

The Victoria Lumber and Mfg. Co., Chemainus, B. C., is having plans prepared for a boiler house to house seven boilers, generating 4,600 h.p., and to cost $30,000.

The town council of Jonquiere, Que., is erecting a hydro-electric power development plant at a cost of $75,000 and will instal 1,500 and 1,800 h.p. turbines. J. M. Lacroix is clerk. J. F. Grenon, Cincinnati, Que., is engineer.

Halting Depreciation in Refrigerating Plants

By I. N. HULL

Practical Considerations the Operating Engineer Should Heed in Overhauling the Apparatus in Order to Retard Natural Wear and Tear

THE purpose of overhauling and repairing all parts of the mechanical equipment in ice making and refrigerating plants is twofold. In the first place, the various parts of the mechanical equipment may be operated at their highest efficiency only when they are in perfect mechanical condition. In the second place, the natural depreciation of the apparatus, that is, the natural wear and tear, will be retarded appreciably when all parts of the equipment are functioning properly.

In order that the operating engineer may ascertain accurately the operating efficiencies, defects in operation, etc., of all parts of the plant, it is necessary to study the plant thoroughly during the operating season, and at the same time keep an accurate record of the pressures, temperatures, etc., in all parts of the system.

By means of an accurate record of the temperatures, pressures, etc., of all parts of the system, the engineer will be able to determine such items as follows: The correct condenser pressure, the difference between the condenser pressure in his plant and the correct pressure, the most economical suction pressure, the difference between the most economical suction pressure and the one which he is carrying in the plant, the correct horsepower required for compressing the refrigerant, and the difference between this and the amount which he is actually expending in the plant, etc. By this method of procedure, he will be able to determine whether or not the conditions in his plant are normal or abnormal.

Must Keep Log

Also, during the operating season, he should study thoroughly the functioning of each and every part of the mechanical equipment. Any defects in the operation of the equipment should be noted and marked on the engine room log, or some suitable notation made. By keeping these permanent records of the operation of the different parts of the plant, the engineer will not only be in a more intelligent position to discover the defects of operation, but will be in a better position to eliminate or remedy them.

In reference to the type of engine room log to be used for any particular plant, it is to be observed that it is probably true that each particular plant should have its own individual engine room log. Although the plants may be used for the same purpose, this is useful in determining any defects in the mechanical equipment or working temperatures and pressures of the system. Therefore, the operating engineer should develop and maintain his own engine room log for his particular plant.

The engine room log should not contain too many items which tend to make the log not only complicated, but also would require too much labor to secure a proper record. The reading of the different gauges, thermometers, etc., should be taken every three or four hours, since the load on ice making and refrigerating plants is fairly constant during the period of a day.

To Tabulate Defects

After the operating engineer has secured and maintained his engine room log, and made all suitable notations relative to defects in the various parts of the plant, it is advisable for him to tabulate in some suitable manner those things which he deemed advisable to overhaul and repair during the slack season of the year. By going about his work in a systematic manner, according to a definite program, the engineer will find that his work will be lessened and at the same time none of the important items will be overlooked.

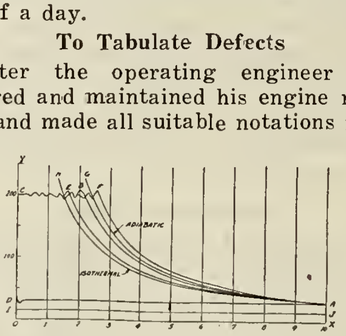


FIG. 1

A list of the mechanical equipment in any particular plant will be individual with the plant. On the other hand, the following items may be found helpful in making up a list for any particular plant:

High Pressure Side—Compressor; crank shaft; flywheel; ammonia condenser; ammonia condenser pan; oil interceptor; ammonia receiver; ammonia connections.

Low Pressure Side—Tank and partitions; brine coolers; tank coils; cans and can covers; brine agitators; can filler and hose; core suction pump; air piping; air connections; air blowers; filters; storage tank; water connections; water pump; can hoist; ice dump; brine pumps; brine piping and connections; direct expansion piping and connections; distilling apparatus.

Power Plant Equipment — Steam engines; boilers; boiler feed pumps; feed water heaters; steam exhaust connections; water connections; electric motors; internal combustion engines.

Miscellaneous—Ammonia; brine; insulation, etc.

Since the main compressor is probably the most important part of the compression refrigerating system, considerations relative to the inspection and overhauling of this unit will be given first. Also it is evident that the compression refrigerating system contains the majority of the moving parts of the system, so that it is reasonable to expect defects in the different parts of the compressor relatively sooner than in any other part of the system.

Indicating the Compressor

The action of the valves, packing, piston rod, connection rod, and main bearings should be observed closely while the machine is in operation, so that any irregularities may be carefully noted. One of the best methods of studying the action of the inside parts of the compressors is that afforded by the pressure indicator. The action of the valves and piston rings may be studied by this means.

If the compression of the vapor occurred in a cylinder which is composed of a non-conducting envelope, so that the refrigerant could neither absorb nor reject heat as such during compression, the compression curve on the indicator card would follow the adiabatic line, AG, shown by Fig. 1.

Under practical conditions, however, there are temperature differences between the vapor of the refrigerant and the metallic parts of the cylinder. Therefore, there will be some heat transmission between the parts, which, together with some other factors, tend to affect the relation of the actual compression curve to that secured under adiabatic compression. In general, it will be observed that when the compressor is in perfect mechanical condition, and when it is operated on the dry compression system, the actual compression curve will be only slightly below the true adiabatic curve.

This compression under actual conditions is represented by the line, AB, on Fig. 1, which lies near the adiabatic compression curve. The other reference curve is known as the isothermal curve, and is the curve which would show the relation of the pressures and volumes during compression at a constant temperature. The isothermal curve is shown on Fig. 1 by line AH.

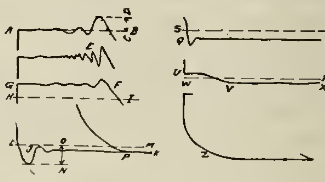

FIG. 2

With Clearance Reduced

All of the diagrams shown by Fig. 1 are assumed to have been taken from a compressor which has clearance reduced to the minimum. An indicator card such as shown by AFCD of Fig. 1 may be secured under some conditions of operation. By an inspection of the compression curve, AF, it will be noted that the pressures build up in the compressor cylinder faster than they should as the piston proceeds through the stroke. This condition could evidently be caused by the leakage of high pressure gas from the condenser back into the compressor cylinder during the first part of the discharge stroke. Also, practically the same effect would be noted should the gas leak past the piston from the opposite end of the cylinder.

Again, a diagram similar to the figure AECD might be obtained. By comparison to the theoretical adiabatic compression curve, it will be noted that the pressures do not build up as fast as they should, as the piston progresses through the stroke. It is evident that this condition may be produced by the leakage of the high pressure gas from the cylinder. This leakage may occur through the suction valve into the suction line, or through some other joint into the region of low pressure. The foregoing relate to defects that may be discovered by a study of the compression curve on the indicator diagram.

Discharge of Gas

It is interesting to note the defects which may be discovered by observing the line on the diagram which represents the discharge of the gas from the cylinder. In Fig. 2, the average condenser pressure is shown by line AB. The distance CD indicates the relative increase of the pressure in the cylinder above that in the condenser which is necessary to open the discharge valve. This condition may be produced by a sluggish or slow action of the valve, due to binding or sticking.

A tendency for the discharge valve, or other parts of the mechanism to vibrate is shown by E in Fig. 2. The same effect also may be produced by defects in the indicator mechanism. In some compressors, the gas may encounter too much resistance as it is being forced out of the cylinder.

The velocity of the gases through the passages in the cylinder may be exceedingly high, the valve spring may be too strong, or the valve may be too heavy, etc. Under these conditions, the pressure inside the cylinder must be considerably above that in the condenser during the entire discharge stroke. This condition is shown by line FG as compared to line HI of Fig. 2, line HI representing the average condenser pressure.

Study Suction Line

In a similar manner, the suction line may be studied in order to determine defects in the operation of the suction valve. If the suction valve sticks, or binds, the pressure in the cylinder may have to be reduced considerably below that of the suction line before the valve will open and the vapors of the refrigerant will flow into the cylinder.

The line ON of Fig. 2 shows a reduction of the pressure at the beginning of the suction stroke, while line JK shows the pressure during the remainder of the stroke under these conditions. Also, the suction valve may stick or bind so that it does not close until the piston has started on the compression stroke for a considerable distance. This is shown by the line KP.

If the suction valve spring is too strong, the pressures as shown by the lines OR and ST will be obtained, line ST representing the suction pressure in the suction main, and OR the pressure in the cylinder. If there is considerable leakage of the gas past the piston, or through the discharge valve from the condenser the pressure in the cylinder will not be reduced enough to allow the suction valve to open, until the piston has traversed a considerable portion of the stroke. This condition is shown by line UVX of Fig. 2.

Sometimes the leakage of the gas past the piston or from the discharge valve will not allow the pressures in the cylinder to be reduced as rapidly as they should. This gives a rounded expansion curve which is shown at Z in Fig. 2.

In the ultimate analysis, it will be noted that the engineer must not only be able to get a card which gives a picture of the conditions in the cylinder, but also be able to study and analyze all of the lines shown by the diagram.

Overhauling the Compressor

After having observed the functioning of the parts of the compressor in the foregoing manner, the compressor may be shut down at any convenient time for overhauling. The packing, piston and piston rod should be removed and subjected to close inspection. The relative condition of the packing is shown not only by the condition of the packing itself but also by whether or not the piston rod is worn and has shoulders. If the piston rod presents a highly polished surface, and is not worn appreciably, it is generally an indication that the packing is functioning in the proper manner.

If Rod Is True

In the event that the rod is true and not worn, a good form of metallic packing may be used to advantage. On the other hand, if the rod is worn considerably or is out of line with the centre of the machine, it may be advisable to pack the rod with eccentric fibrous packing rings in order to compensate for the misalignment and the wear on the rod. Of course, if it is considerably worn, it should be refinished and a new set of packing installed.

The proper functioning of any packing for the stuffing box on the compressor piston rod depends upon the presence of an oil film. The oil film under this condition serves really two purposes: first, to prevent the leakage of the medium under pressure, and second, to reduce the friction between the two solid surfaces. Therefore, in selecting and using packing for the compressor piston rods, one should bear in mind the true principle of any good packing for the compressor piston rods, and remember that it is not consistent to use a frictional material which depends upon the pressure between the two surfaces for prevention of the leakage of the medium under pressure.

Selection of Packing

Another consideration to be taken into account in the selection and use of packing is that of the temperature of the rod and compressor. In actual operation the compressors are subjected to different temperatures, due to operation on wet, dry or superheated vapor. The packing should have sufficient resiliency to maintain a tight joint under the foregoing conditions of temperature.

There are many types of ammonia packing which may be used to pack the stuffing box of compressors, pumps, valves, etc., in refrigerating plants. Among the types which are available at present, the following are the most important: collapsible tube metallic, flexible metallic, elastic metallic, fibrous or soft, and combination types.

The suction and discharge valves should be inspected closely. Generally, it will be necessary to grind them to a perfect seat and adjust the spring for quiet operation. The seat between the valve case and cylinder head must also be examined and, if found not perfect, it should be ground to a perfect seat. The piston rings should be inspected, and if they are found to be worn considerably and are loose in the grooves on the piston, they should be replaced by new rings. The inside walls of the cylinder should be examined for wear. If the surface has a high metallic polish, it is an indication that the cylinder is being lubricated properly and that the piston rings are mechanically perfect.

Have Cylinders Re-bored

In some cases, which is especially true of the larger types of horizontal machines, the cylinder will tend to wear out of round, under which condition, at suitable intervals, it is advisable to have the cylinders re-bored and re-finished. The condition of the bearings between the frame and the crosshead should be observed. As the wear goes on at these points it is sometimes necessary to re-babbitt the crosshead shoes, or to move the crosshead shoes so as to compensate for the wear. The main bearings should be inspected. In the event that these are considerably worn, they should be re-babbitted and re-finished. In the case where they are only slightly worn, it is generally possible to make adjustments, to make the bearings smooth, and to re-cut the oil grooves. Keys, wedges, bolts, etc., should be placed in such condition that they may be used for making the proper adjustment during the coming working season.

In the main, the work of overhauling the compressor consists of examining thoroughly and putting into serviceable condition each and every part of the compressor which may be subjected to wear.

Progress in New Power Equipment

ELECTRICAL EQUIPMENT

A MARKED advance in the elaboration and design of interior wiring and electrical equipment is presented in the recent completion of the Buckingham apartment house in Toronto.

This building contains thirty-four suites, and a very complete electrical installation throughout has been planned, with electric ranges, fixtures, and refrigeration supplied to all tenants.

The fixtures supplied in the suites are of the candelabra type and are a very attractive feature. Each suite has the following outlets: living room, four brackets, one switch and two base plugs; first bedroom, two brackets, one switch and two base plugs; second bedroom, two brackets, one switch and two base plugs; bathroom, one bracket, one switch and one outlet for electric heater; kitchen, one centre light, one switch, one outlet for electric iron and one outlet for stove.

The wiring throughout the entire building is installed in iron conduits, a one inch conduit containing three No. 6 double braid cable being distributed from the main board in the basement to an iron cut-out cabinet in each suite.

The electrical distributing board is an exceptionally fine installation. It consists of an iron gutter box 18 feet long by 14 inches high and 10 inches deep. In this cabinet, an illustration of which is shown, are mounted two 2 inch by ¼ inch buss bars in parallel for each leg of main feeders. These buss bars are held in place by ⅜ inch sheet fibre 14 inches by 10 inches, with slots cut for the buss bars to pass through. Switch connections are made with No. 6 cable, both ends of which are soldered into 60 ampere lugs.

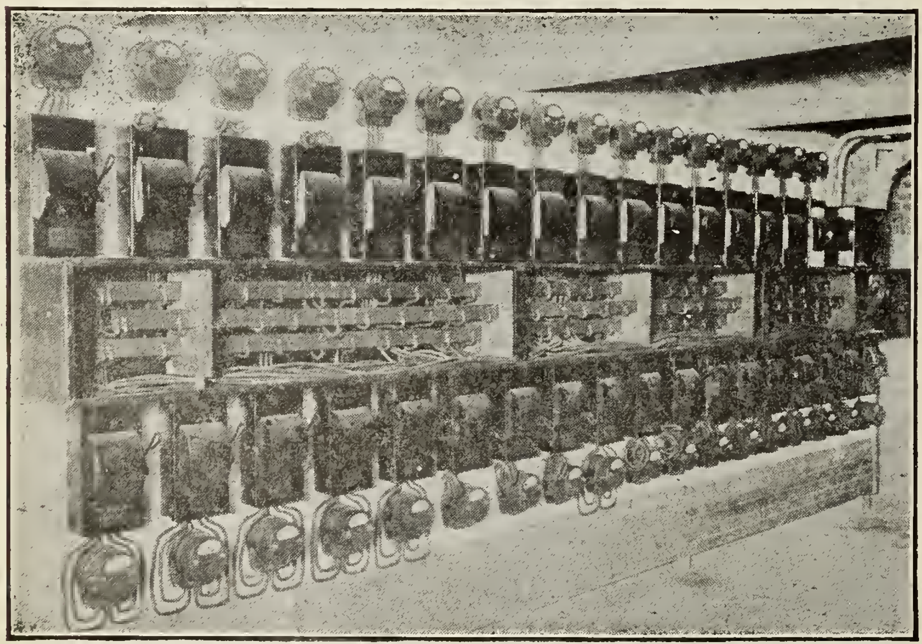
A slot is provided in the gutter box to provide ready access to the wires from the gutter box through the service switches to the meters and return. A metal bushing with flanged end forms a connecting link through this slot between service switch and gutter box. A strip of fibre with holes for the wires of the meter loop is mounted on the service switch.

This box and service equipment was designed and supplied by the Canadian Drill and Electric Switch Box Company, 1402 Queen St., East, Toronto. The service switches are of 60 ampere capacity and the main service switch is of 1,000 ampere capacity.

The main feeder leading from main service switch to the distributing board, a distance of approximately 50 feet, consists of three 1,000,000 single conductor rubber covered lead cable in a four inch conduit pipe.

Approximately 20,000 feet of conduit, 50,000 feet of wire, 1,038 outlets, 250 switches and 175 receptacles were used in the equipping of this building.

The suites are each served with a Bell telephone outlet as well as a private telephone to the main entrance, the Bell service of an underground 100 pr. lead cable from Queen Street connected to a distributing cabinet 36 inches by 36 inches by 5 inches and ¾ inch conduit runs from this cabinet to the various suites.



Distributing board recently constructed by the Canadian Drill and Electric Box Company, for installation in the Buckingham Apartment House, Toronto, marks a considerable advance in electrical equipment

The power wiring for 550 v., 3ph., 25 cycles supplies power for ice machine and the circulating pump for heating system.

The oil burning equipment has two ½ h.p. motors using 220 volts.

The complete installation was made by the Roxborough-Dean Ltd., 36 Front St., East, Toronto.

DAMPER REGULATORS

One of the later developments in the science of combustion control is the automatic control of the damper by means of the Craig damper regulator. This regulator, as applied to furnaces using forced draft, will maintain a constant pre-determined suction over the fire within two one-hundredths of an inch of water, regardless of load variations on the boiler or changing furnace conditions.

Although sensitive in operation, the Craig regulator requires little attention. By keeping a low constant draft over the fire not only is high CO_2 obtained and excess air cut down to a minimum, but the brickwork is protected against destruction due to sudden temperature changes.

The operation of the regulator is briefly as follows: From the furnace a two inch pipe leads under a zinc bell immersed in water. This bell is connected to a control piston and the two counterbalanced and compensated for buoyancy by suitable weights. The bell is of such size that the slightest variation in furnace draft results in a corresponding change in the position of the bell. The bell transmits its change of position to the control piston, which controls the water which operates the main damper piston. This piston is connected to the damper by cable. Thus the damper is opened or closed accordingly. The construction of the regulator results in the quick opening of the damper and slow closing. Any sudden pressure in the furnace results in the damper flying wide open. This gives protection in case of tube failure. The slow closing action eliminates the possibility of a pressure building up in the furnace.

RAPID PRESSURE FILTERS

There has been during the past year an increasing demand for small, easily operated, rapid pressure filters in small industries located where the water supply is taken from a creek or river, which is at times muddy. To meet this demand the Refinite Co. of Canada have designed and marketed a small steel

shell filter with a single control valve.

The shell is made entirely of steel with electric welded joints, insuring a strong and durable container. The sand and gravel rests upon a steel diaphragm plate in the bottom, containing Refinite, two-piece, crown-head, brass sand valves, which are strong and durable. The usual depth of sand bed is used.

The single control valve permits easy operation of the unit, and no confusion can exist when performing the required operations during washing periods. The valve is controlled by one lever with a pointer attached operating in connection with a dial on which is plainly marked the various operations. This valve is constructed upon the cock principle, and is very durable and simple in construction.

These filters are also equipped with a sight glass to observe the condition of the water, and a coagulant feeder for mixing with the raw water the necessary aluminum sulphate, which insures more efficient filtration.

Larger units are constructed similar to these smaller ones for large industries. They do not contain the single control, however, because from experience it has been proven that this type of valve is not efficient in the larger sizes.

MECHANICAL STOKERS

During the past year the Under-Feed Stoker Co. of Canada have perfected an entirely new type of electrical drive for underfeed stokers. This drive replaces the devices heretofore in use and is so designed as to retain all the best features of stoker practice. It allows of entirely automatic, individual control of each retort, and in cases where exhaust steam is undesirable, or in low pressure and heating plants where boiler pressure is insufficient to operate the stoker rams, it provides an entirely satisfactory and desirable drive.

A small one h.p. reversible motor is mounted on top of the outer end of the stoker, and, by means of roller chain, drives a large screw threaded shaft on which rides a nut fixed to the ram. The motor is operated in one direction to pull the ram out and is reversed to drive the ram in. A release device is provided which prevents the ram from overrunning.

The forward and reverse movement of the motor is governed by a special revolving contactor which is usually driven from the forced draft fan shaft, but may be operated by a small separate motor if desired.

The contactor is operated by means of an adjustable ratchet device so that the amount of coal may be adjusted by hand if desired, and where the fan is driven by a constant speed motor the stoker can be automatically controlled.

Where the fan is driven by a variable speed motor or a steam engine the coal feed varies with the amount of air delivered, as the contactor is driven directly from the fan shaft and keeps step with the fan at all times.

This electric drive provides for the necessary quick inthrust of the coal and consequent breaking of the fire, so essential in good firing, and uses less than 1-3 h.p. per hour, due to the fact that the motor stands idle for a great part of the time.

There are four moving parts to the stoker—ram, nut, screw and chain drive. All these parts are completely enclosed and are self-lubricating.

The contractor switch is of the oil-immersed type and is very simple and rugged in construction.

WATER SOFTENERS

Many improvements have been made on Refinite Zeolite water softeners during the past year, with the result that the units now have a larger capacity, with the space required for installation reduced to a minimum. The efficiency has also been increased due to a change in the direction of the flow of the water through the softener.

The direction of flow was changed from a downward to an upward flow after making laboratory and practical experiments. The latter method of operation was found to be superior to the former for the following reasons:

The pressure of the raw water in flowing up through the refinite mineral bed separates the mineral grains from each other, thereby allowing the water to come in contact with the entire sur-

face of each grain, insuring maximum softening efficiency.

The raw water first flows through the strainer system which is in the bottom of the softener container, and any dirt or foreign matter which might be in the raw water is caught before it enters the mineral bed.

The possibility of channeling is entirely eliminated, because the raw water is uniformly distributed through the strainer system, which equalizes the pressure throughout the mineral bed, reducing the packing tendency to a minimum.

The raw water coming in contact with the lower portion of the mineral bed first would contaminate this portion the most. The brine solution enters the softener container near the bottom and purifies this portion of the mineral bed first before continuing through the mineral bed and purifying the remainder of the mineral. This feature is very important, because maximum regenerating efficiency is thus obtained.

Flanged valves and fittings are now used exclusively for the valve nest on softeners. This type of fitting permits an easy assembly of fittings, and allows any part which might become damaged to be removed without dissembling the entire nest.

The steel containers are equipped with a steel diaphragm plate in the bottom, containing Refinite two-piece, crownhead, brass sand valves, which are strong and durable. The mineral bed rests directly on this plate. All concrete fill which was formerly necessary when the old manifold pipe system was used for water distribution has been discarded entirely.

CANADA STOKER SALES

"Business during the past year has been good, although it could be better in some localities," stated W. M. McRobert, sales manager of the Canada Stoker Co., recently.

The Canada Stoker is simple in operation and readily adaptable to boilers, especially of the horizontal return tubular type.

In operation, fuel is fed to a hopper of about 450-lb. capacity, usually two hoppers to a boiler. Directly under each hopper is a simple reciprocating feed plate actuated by an eccentric and curved vertical arm. Power is supplied from a shaft driven by a roller chain.

The to-and-fro motion of the feed plate causes the fuel in the hopper to slowly work down on a flat table surface, formed integral with the stoker. The fuel is then gradually pushed along by the action of the feed plate until it reaches the revolving blades of the stoker.

These blades, revolving at about 270 r.p.m., strike the fuel as it is fed and deliver it continuously to the furnace in a manner which might be likened to a light shower of rain. The different curvature of each blade distributes the fuel over the full grate area.

The blades operate at a constant speed, and are independent of the feed plate and control device.

The rate at which the fuel is supplied to the distributing blades is governed entirely by the fuel control hand-wheel, varying from nothing to a ton or more per hour. A simple feed latch may be instantly disengaged, stopping all feeding at once.

The advantages claimed over hand firing are as follows:

Even and constant supply of fuel to the furnace with the doors closed.

Uniform supply of air to the fuel bed with the fire doors closed.

The absence of black smoke.

Ability to use low-grade fuels which cannot be burned when fired by hand.

A constant steam pressure.

Ability to maintain a thin fire not over 4 inches in thickness, giving the best possible combustion.

In the chain grate stoker, made by the Canada Stoker Co., many improvements have been incorporated.

The stoker is designed with special air seals both at the sides and rear of the grate, hence all the air required for combustion must pass through the stoker links.

The links can be readily renewed while the stoker is in operation.

Either natural or forced draft may be used with the stoker.

A special feature of the stoker is the continuous drive. A totally enclosed removable gear case with 7 changes of speed, varying from 1½ to 12 inches of grate travel per minute is provided. This feature is of particular value in power plants having large variations in load.

The grate links are narrow and deep, giving maximum air space, evenly divided. The diagonal ribs give rapid combustion with minimum sifting of fine fuel.

Miscellaneous

The John T. Hepburn, Ltd., Toronto, propose an extension of their foundry by taking in a section of their plant formerly used for storage. A large new tumbler was recently installed in this foundry, and a new molding machine for which the company has secured the Canadian manufacturing rights, will shortly be brought into service. The Hepburn foundry has been running continuously since the war, chiefly on engineering work. A notable job going through at present calls for the production of 1,164 chain pieces, each weighing 250 lbs. For the Toronto incinerating plant 250 tons of castings are being molded and machined.

John T. Hepburn, Ltd., are erecting the steel work for the Northern Canada Power Co.'s new sub-station at Shumacher, Ont.

Orders for Canada stokers have recently been received from Lever Bros., Toronto; St. Croix Soap Co., St. Stephen, N. B.; J. H. Dunlop & Son, Co., Richmond Hill, Ont.; Canadian Industrial Co., Corbyville, Ont.; C. Turnbull Co., Galt; Western University, London; H. J. Mills Co., Richmond Hill.

S. B. Nichol, John St., Blenheim, is in the market for electric motors for planing mill.

A. Milne, Blythe, is in the market for complete equipment for a hydro-electric lighting and power distribution system for the council. The work will be under the direction of the Ontario Hydro Commission, London, and the estimated cost is $28,000.

The Council, Cayuga, A. Coulter, Reeve, contemplates the installation of a hydro-electric system at an estimated cost of $30,000.

MOTORS with Experience

The question you ask of a man whom you expect to place in a responsible position is—"What is your experience?" So you should ask about motors. Experience—over thirty years of it—ten million horse-power of it—is a big item in Westinghouse motors. The instinct for technical rightness, the know-how, the beauty of mechanical and electrical competence—these things, that experience only can provide, are the fundamental superiorities in motors that bear the Westinghouse mark.

Why Is Low Power Factor Penalized?

A factory load of 350 Kw. at 70% power factor requires station equipment and transmission line capacity, that at 100% power factor would deliver 500 Kw. To compensate the Central Station for the 150 Kw. of plant rendered unavailable for revenue by the low power factor the consumer is charged an amount, and properly so, in excess of his bill for energy used. This charge in excess of the power bill is in the nature of a penalty for low power factor and is a 100% loss to the consumer.

The installation of a C. G. E. Synchronous Condenser of 200 Kv-a. capacity would, as shown in the diagram below, bring the power factor up to above 91%, that is, above the penalty point, would reduce the power bill by the amount of the penalty and in addition improve the voltage regulation and the factory lighting. Any consumer penalized for low power factor may obtain reliable engineering information and data on matters of this nature by referring to our nearest sales branch.

Making front door arch of Plibrico.

DISTRIBUTORS: Beveridge Supply Co., Ltd., Montreal; Shell Bar Boico Supply Co., Ltd., Toronto; Evans, Coleman & Evans, Vancouver, B.C.; Winnipeg Supply and Fuel Co., Winnipeg; Building Products & Fuel, Ltd., Saskatoon; Dominion Lime & Coal Co., Regina, Sask.

Why fire brick can never rival Plibrico—

SUPPOSE you could weld all of the bricks in your furnace together in one solid mass—wouldn't it be a far better furnace? Wouldn't it last far longer with the joints as good as the brick?

Plibrico eliminates those weak spots—the joints. No furnace—regardless of the quality of fire brick used—can be better than its weakest joint. And therefore fire brick can never be made good enough to even rival jointless Plibrico.

It is pounded into any shape desired with a mallet, then troweled smooth. Heat vitrifies it into a rock-like, air-tight, gas-tight lining that resists temperatures to 3,100° F. Use it wherever fire brick can be used.

Plibrico is delivered only in steel containers of distinctive appearance, as shown opposite.

Cash Reducing and Regulating Valves

Cash Standard Regulators range from simple reducing valves to auxiliary controlled regulators, engine governors and similar reducing and regulating specialties. All embody principles that have been proved unsurpassed by years of extensive use. The catalog tells why they can't stick or bind — why wire drawing is greatly reduced—why regulation is dependable and service life longer. Write for it.

The Craig Damper Regulator

By keeping the damper automatically adjusted to the point of highest combustion efficiency, Craig Damper Regulators pay enormous dividends. The Craig employs the proper regulating medium — velocity over the fire. The installation increased average CO_2 two per cent., effecting a coal saving that quickly paid for the equipment — and this was in a plant where the dampers had always been intelligently and carefully regulated. Ask for the catalog.

MOREHEAD RETURN TRAP

Will Rectify and Raise the Efficiency of Any Steam Service

THOUSANDS OF TONS of coal are saved annually in the plants which are MOREHEAD equipped

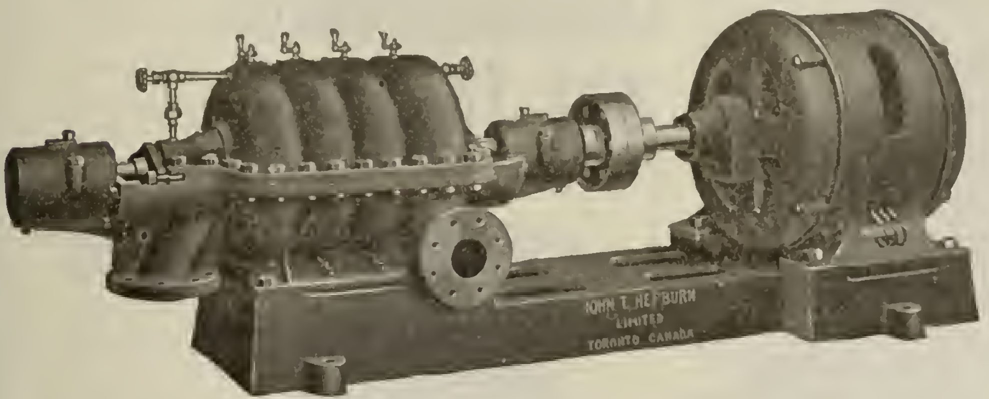
34 Years on the Market—Known the World Over

J. E. FARRELL DIRECTOR OF SALES
304 Manning Chambers, TORONTO, ONT.

On the Job Fifty-two Weeks Each Year

HEPBURN products have merited in the past and are now maintaining their enviable reputation for high efficiency and long, unfailing service.

Illustrations are typical of the lines in which we specialize.

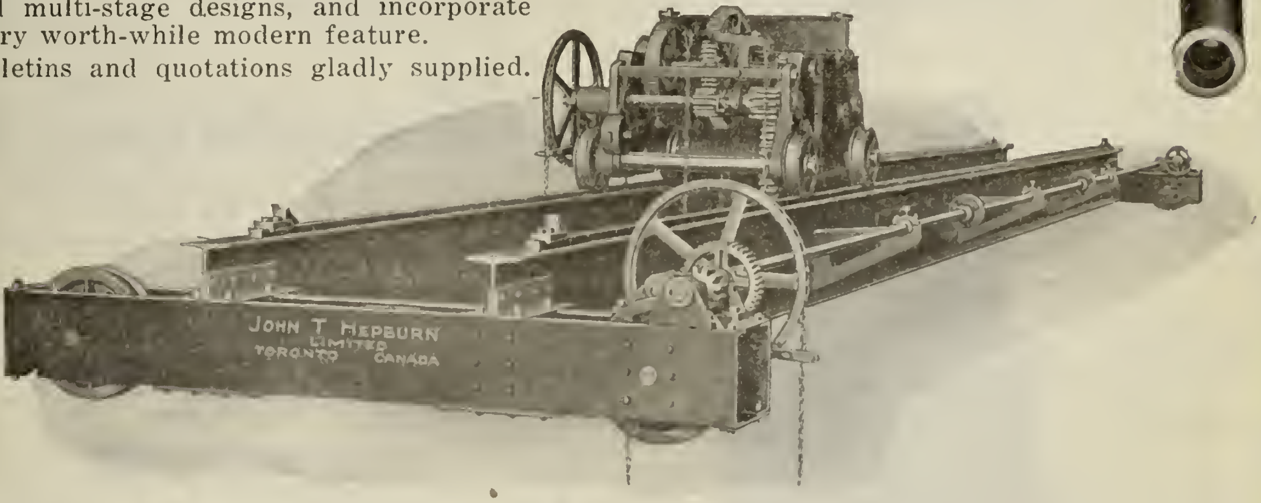


Hepburn Fire Hydrants are widely recommended as standard equipment for all services.

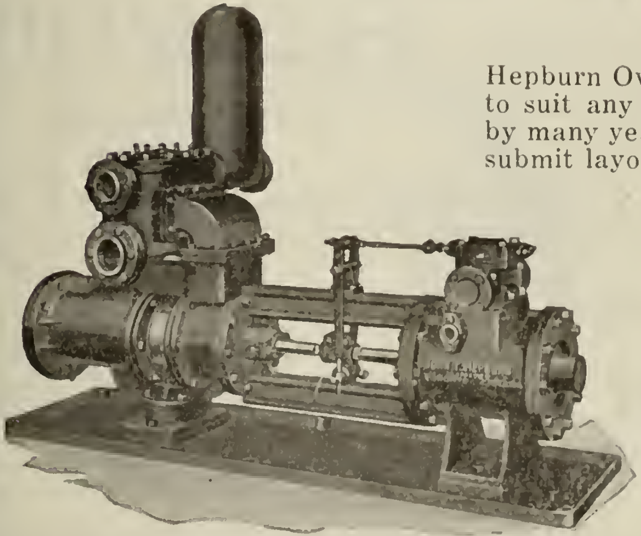
We can give you attractive prices on any quantity.

Hepburn Centrifugal Pumps are made in single stage, single and double-suction and multi-stage designs, and incorporate every worth-while modern feature.

Bulletins and quotations gladly supplied.



Hepburn Overhead Cranes and Heavy Duty Derricks are built to suit any condition of service. Our engineers are backed by many years of experience in these lines and we will gladly submit layouts and estimates.



Hepburn's Reciprocating Steam Pumps are built for boiler feed, vacuum and general service, in a variety of types and in all sizes.

These are illustrated and described in our general catalogue, which we will mail promptly on request.

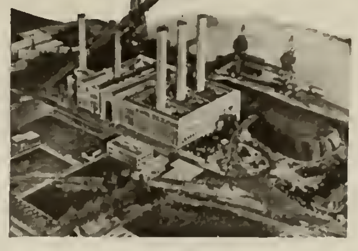
Fewer Shutdowns

when you have

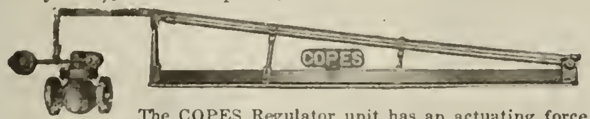
COPES



One of the many well-known COPES users—Consolidated Gas, Electric Light & Power Co., Baltimore, Md. They have 70 COPES.

No important power plant, large or small, can afford to risk "shutdowns." That's why nearly all important plants use the COPES System of Boiler Feed Water Regulation.

Being the simplest and most rugged regulator, COPES gives boiler feeding that is continuous — practically 100% "trouble-proof."



The COPES Regulator unit has an actuating force 100 times greater than the valve resistance— COPES is entirely free from lag. Every COPES Regulator is guaranteed to pass the required amount of water at a given pressure drop.

Savings of 2% to 8% in fuel are reported after installing the COPES— also savings in labor, and increased boiler efficiency.

By fuel savings alone, the COPES will quickly pay for its installation in your plant. Let us estimate the savings that you can make. Write today for Catalog D.

NORTHERN EQUIPMENT CO., 112 West 11th St., Erie, Pa.

SIL-O-CEL
TRADE MARK REGISTERED U.S. PAT. OFFICE
A CELITE PRODUCT

162 Tons of Coal Saved per Year

QUANTITIES of fuel consumed in combustion never become productive. Heat is generated, but all of it is not utilized. From every surface there is constant heat radiation,—a source of unnecessary waste.

Sil-O-Cel Insulation forms a barrier to heat leakage, and in stopping this loss saves fuel. Take for example, an ordinary 500 H. P. Boiler. The fuel savings accomplished by installing a course of Sil-O-Cel Insulating Brick through the walls and over the tops of such a boiler will average 162 tons of coal saved per year. Savings are proportionate with other fuels—and in kilns, ovens, furnaces, oil stills, etc., the savings are even greater.

The facts regarding Sil-O-Cel show it to possess lower conductivity than any other insulation and adapted to all types of equipment without change in design:

Insulating Value — Powder 0.30; Brick 0.58 B. t. u. per sq. ft. per hr. per inch thickness per degree F. difference in temperature (U. S. Bureau of Standards), or one-tenth as conductive as firebrick inch for inch.

Resistance to Direct Heat—Brick and Powder 1600° F. *without shrinkage.* Brick 2200° F. *without shrinkage.*

Melting Point—2930° F. (1610° C.) U. S. Bureau of Standards.

Weight—Powder 15 lbs. per cu. ft. packed in place; Brick 1¾ lbs. each, equivalent to about 30 lbs. per cu. ft.

Crushing Strength—28 tons per sq. ft.

Forms—Brick, Block, Powder, Cement.

C-22

A request will bring Bulletin CW-6 *containing complete information. Use the coupon or write nearest office.*

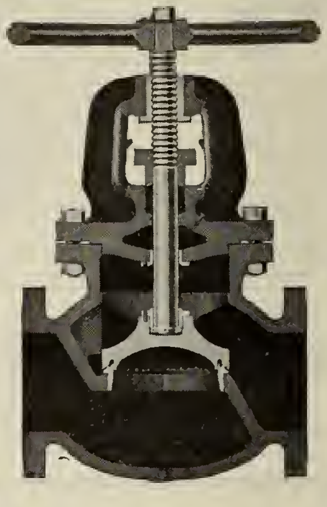
EDWARD *Extra Heavy* Cast Steel Stop Valves



Superior Valves for Exacting Duty

Designed to offer the least resistance to the flow, with full sized opening through seat, with body, bonnet and gland made of Electric Steel and flanges drilled in accordance with American Extra Heavy Standard of 1914, these EDWARD Stop Valves will give satisfaction under the most severe service.

THE EDWARD PROTECTED SEAT AND DISC

This positive protection of the most vital organ of the valve—the seating surface — is used only in Edward Valves. It prevents cutting from wire drawing, especially under high pressures and temperatures where very small leaks rapidly grow owing to the terrific erosion action.

Send for descriptive catalogue of the Edward line.

60 Towns in Ontario Protected!

OAKVILLE, Ontario, like 60 other Ontario towns, has no fear of water shortage. The town pumping station has been equipped with a STERLING internal combustion engine. Should the regular pumping system fail, or be shut down for overhauling or repairs, or in case of fire, a STERLING engine is standing by ready for immediate duty.

The illustration shows a STERLING Engine driving alternately either a lighting generator or a Goldie & McCulloch Co., Ltd., Rees RoTurbo pump of 1,200 G.P.M. capacity in the pumping station at Oakville. Speed is 1,200 R.P.M.

STERLING Internal Combustion Engines, direct drives for generators, and centrifugal pumps, when employed for peak load and standby, can save in the cost of power.

Fire your boilers economically, according to the normal load and use STERLING engines on peak load. Operate the STERLING steadily when overhauling the boilers or repairing machinery. Use the STERLING on the fire pump.

In Emergency

Oakville is finding the STERLING an indispensable standby power plant.

The Consulting Engineers, Messrs. Chipman & Power, of Toronto, wrote:

"We understand that the fire was first noticed about 6.30 a.m., and when the alarm was rung in, the electric energy from the main power line was not in service, having been cut off the main transmission line somewhere outside of the town. The engine was started immediately with the pump connected and gave excellent service throughout."

The Chairman of the Commission said:

"A few minutes after alarm the new pump was delivering 1.150 gallons per minute at 110 pounds pressure. This supplied all the water the six lines of hose could handle.

"The pump ran continuously for two hours, and its performance fully justified the installation of the type of motor and pump."

Costs About $20 a Horsepower **No Maintenance Cost**

Sterling Engine Co. (Dept. C4) **Buffalo, N.Y., U.S.A.**

FOR INSTANCE—

One large Canadian paper mill had this fire brick problem.

10 B and W boilers 500 H.P.; fired with fuel oil.

When this plant was built we recommended ELKO SPECIAL for this equipment.

They have had such complete satisfaction they have used ELK FIRE BRICK exclusively ever since.

This is only one little instance. Mill reference on request.

What's Your Problem?

Dunham Radiator Traps Insure Service that is Noiseless—Sure—Lasting

The Dunham Two-Part Radiator Trap

Made in five sizes as shown. The Nos. 1, 2 and 3 Traps are regularly furnished nickel-plated and with union nut and nipple, threaded right hand. They may be supplied in angle, straightway, right hand or left hand pattern. The body and cover are made of red brass.

The Nos. 4 and 5 Traps are painted battleship gray and furnished in either patterns with female right hand threaded connections, both inlet and outlet. The body and cover are made of the best gray cast iron.

Maximum operating pressure ten (10) pounds gauge.

Dunham Radiator Traps were the first thermostatic disc traps. After 20 years of unparalleled service they are still the last word in radiator trap efficiency. To the heating contractor who has experienced the annoyances of other types we recommend the Dunham Trap as a certain means to personal satisfaction and better pleased customers.

The Dunham Radiator Trap automatically releases all air and condensate and retains the steam within the radiator. Its construction is simplicity itself. Write for detailed technical information to-day.

Flue gases can be reduced 50 degrees by careful firing and clean boiler surfaces

Such is the substantial saving that can be effected by recording and measuring your flue gas temperature with

TRADE MARK
BRISTOL'S
REG. U. S. PAT. OFFICE.

Recording Pyrometers

Of course, the temperature of outgoing gases can be decreased by economizers, or by a change in the baffling — but such changes are costly and the economy depends upon the cost of coal.

The information supplied by Bristol's Pyrometers, as to the temperature of uptake gases leaving the boilers, is of prime importance as an aid to super-efficient plant operation.

Hundreds of Bristol's Pyrometers are recording flue gas temperatures in prominent power plants. Let us tell you more about what they could do in your plant. Our new Catalog O-1401 is waiting for your address.

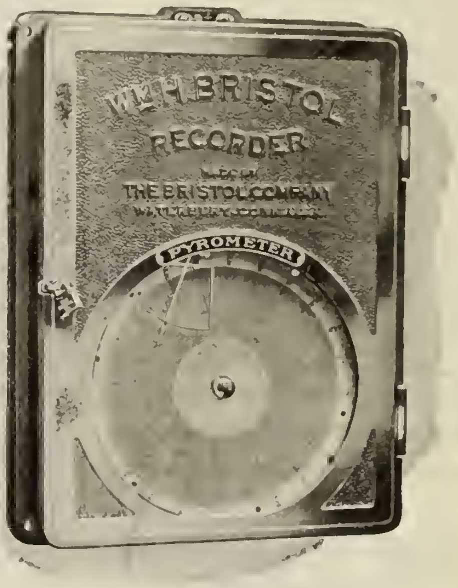

Fig. 1007

A suit has been filed in the United States Federal Court against a pyrometer manufacturer who is infringing patents owned by the Bristol Co. covering Automatic Cold End Compensation for Thermo-Electric Pyrometers.

The Bristol Company, Waterbury, Conn.

$5 May Save You $500 or $5,000!

You work hard for the dollars you save. Properly invested they can be made to work hard for you. But they must be properly invested.

If you feel the need of a guide to show you how to invest your money to bring you the biggest return consistent with safety; to show you how to avoid the pitfalls of investment; you need THE FINANCIAL POST.

It will give you a personalized investment service. Its articles every week will tell you what you want to know about investing. Its discussion of current business and national problems will give you a new angle on economic and political questions. You will have too all the privileges of the Investors Inquiries Department. You may ask as many questions as you like about your own investment and financial problems—the standing of your broker, and the analysis of particular securities, insurance problems, etc. This service is free to all readers.

Stop losing money on bad investments. Invest $5 now where it may save you $500 or $5,000. Pin a $5 bill to this ad. (or your letterhead), write your name and address and we will send you THE POST for one year (52 issues).

The Air Filters Without Moving Parts

DUST AND DIRT IN TURBO-generator and motor cooling air inevitably means loss of productive capacity and constantly threatens to cause short-circuits and damage. You should prevent dust getting into the fine air passages and windings of your equipment. The solution is simple and complete. Midwest Air Filters supply absolutely clean cooling air to your electrical apparatus, and yet require no operating supervision. They have no moving parts, no sprays—no pumps—nothing to get out of order. Let our engineers show you how they will solve your dust problems.

Leakproof!

If your rooms were filled with gas—

WERE it possible to replace the cold or dry air in your storage rooms with inflammable gas, you would have an opportunity to *test* Jamison Doors "under fire."

To learn whether the doors were *absolutely leakproof*, you could pass a lighted torch around the exterior frame of the door. The gas *would not* explode—it *would not* seep through to reach the flame of the torch!

It is well to remember that your *plant* is only as good as its *doors*. The *doors* will either *keep in* profits or allow them to *escape*. "Door Efficiency" is necessary. It minimizes changes in temperature due to leakage and through heat transmission.

Jamison Doors have *proved* themselves *efficient*. They are sturdily built and properly insulated. They bear unusually heavy hardware—three times the weight of the hardware on other doors—and embody exclusive Jamison patented features that make the *hardware* the "strong points" of Jamison Doors.

In equipping *your* plant, give consideration to the door *made leakproof* through its double seals of contact and *kept leakproof* through the practicability of its hardware. We shall be glad to mail you a copy of our catalogue which describes all of the Jamison Equipment, explains their construction, and outlines uses.

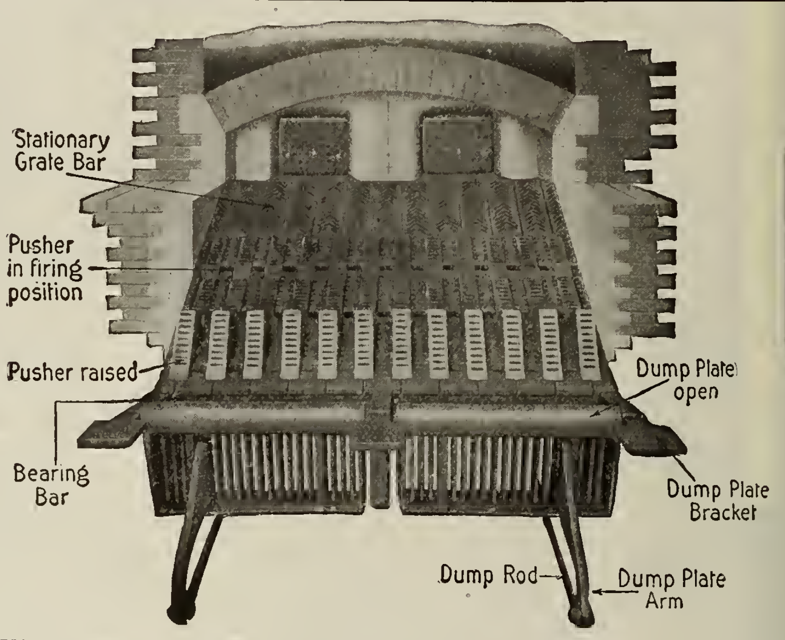
Who uses the National Hand Fired Stoker?

You have been reading our National Hand Fired Stoker advertisements for some months past and you may be curious to know what concerns in Canada use it.

Here is a partial list:

- Imperial Oil Co., Limited, Sarnia.
- Muskoka Hospital for Consumptives.
- Provincial Paper Mills, Georgetown.
- Toronto Golf Club.
- Toronto Hospital, Weston.
- Midland High School.
- Queen's University.
- Cobourg Dyeing Co.
- T. F. Shirley Co., St. Catharines.
- Prince Edward Hotel, Windsor.
- Culverhouse, Ltd., Vineland.

You are at liberty to write any of the above for their opinion of the value of the National Hand Fired Stoker. Booklet, price and full particulars sent on request. Remember, you can use the National under new or present Boilers.



WHAT IT IS

The National Hand Fired Stoker consists of a system of downward sloping grate bars, fuel pushers, dump plates, boiler front, bridge wall and ignition arch. In firing all that it is necessary to do is to dump the fuel on the upper end of the grate and when this is coked it is moved a stage further down by means of pusher rods operated from the front of the furnace, and the fresh charge of fuel may be dumped in.

No need to spread the fuel—any "green" hand can thus do the firing. The successive pusher rods keep the fuel marching downward, ensuring perfect and smokeless combustion, until the lowest or dump grates are reached. The draft is evenly distributed throughout the fire bed and excellent results can be secured with waste and low grade fuels.

You get all the advantages on a smaller scale, and without the great cost of the large mechanical stokers.

View of National Hand Fired Stoker taken from back of fire box looking towards the furnace doors, which are closed. Successive sloping banks of fire grates operated by pusher rods (not seen, because outside the furnace) are shown.

We build Horizontal Return Tubular, Vertical Tubular, Locomotive Type and Marine Boilers. We construct Tanks, Penstocks and Steel Plate work of all kinds. We furnish gray iron and brass castings of any size in the rough or machined to order.

Side dump attachments for "Jones Standard" Stokers

Any user of "Jones Standard" can quickly convert his stokers into the up-to-date side dump type. In place of the hand cleaned dead plates, sloping combustion grates and hand operated dump plates are substituted. The excavation of only a few inches is necessary.

Use the coupon to ask for details.

Its record recommends it

—the best investment for hundreds of Canadian plants

CONSULTING engineers are today recommending stoker firing for plants that a few years ago would have been considered too small for mechanical firing.

Stoker firing is paying big dividends in these smaller plants not alone because coal and labor costs are higher, but also because stokers have been developed to exactly meet the requirements of smaller plants.

The Jones "Standard Side-Dump" Stoker is in every detail an ideal stoker for hundreds of existing plants.

First cost is moderate because of the stoker's exceptional simplicity —the very quality that makes the "Side-Dump Stoker" ideal for smaller plants.

Installation is simple—and therefore inexpensive. No excavation is necessary for ash pits because the simple side dump plates discharge the ash and refuse into shallow pits that are only a few inches below the floor level.

But although this stoker can be purchased and installed at relatively small cost it is nevertheless a real self-cleaning under-feed stoker possessing all the established advantages of the underfeed principle —economy of fuel, quick response to load demands, heavy overload capacity and steady, trouble-free operation.

You will be surprised to find what a small investment is required to convert your plant into an economical stoker fired plant by installing the "Jones Standard Side-Dump" Stoker. Send the coupon for the bulletin.

Put an End to Your Belt Troubles

ARE your transmission costs higher than they should be? Investigate where the trouble lies. Belt slippage and breakage may prove the seat of the cause.

You can eliminate excessive belt slippage and breakage by using D. K. McLaren's Belting. This belting is famous for its toughness and stretch-proof qualities. There is a reason. Every belt is made of the backs of the choicest hide—that portion of the hide which is toughest and free from stretching. In addition, all D. K. McLaren's Belting is British Oak Tanned—the most approved method for making belts that last.

See that your belting is stamped with D. K. McLaren's Oak Leaf. It's your guarantee of economy.

For Thoroughly Dependable Low Cost Power Fairbanks-Morse "Y" Type Oil Engines

These simple rugged power plants are the result of generations of study and experiment by the pioneer builders of Gas Engines. Their entire freedom from Water Injection Systems, Hot Bulbs, Igniters and Timers guarantees an extraordinary low upkeep cost, while their efficient use of low grade fuel oils ensures a dependable supply of power at minimum expense. And they develop power day-in-and-day-out independent of temperature, weather, coal shortage or failing electric supply.

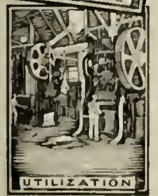
"Let's Both Go"

Says the Progressive Engineer to the Boss. "We'll learn a lot about getting more power at lower cost—we'll examine the new equipment, and get acquainted with the people we buy from. They will be at the

POWER SHOW



December 3-8, 1923

Grand Central Palace
NEW YORK

NOT only the engineer, but the manufacturer, capitalist, dealer and consumer will learn something worth while at this great display of apparatus for creating and handling power.

A great deal of the equipment will be shown in operation under actual working conditions, and there will be trained men to explain the fundamentals of operation.

In these days of high-priced coal, anything that shows how to save fuel is of vast importance. What you will learn about this one thing alone will be worth the trip to the Power Show.

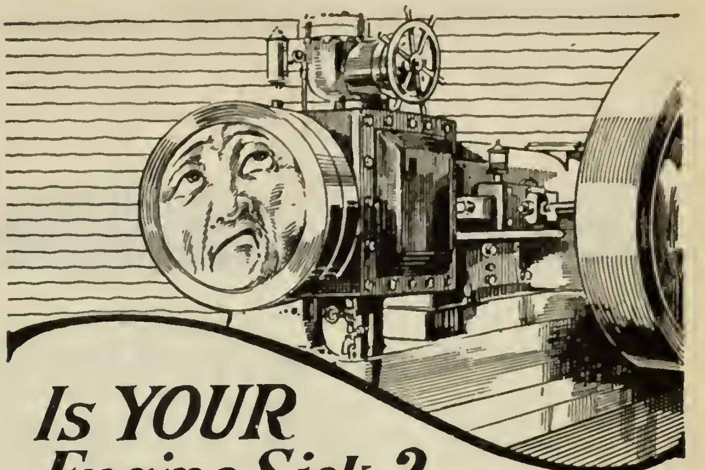
Keep up with the March of Progress! Stay in the lead by keeping posted. Come to the Power Show!

To Manufacturers! If you have something of positive merit and capable of comparison which is used either in producing, transmitting or using power or some mechanical equipment, or supply or materials used by the mechanical industry we welcome you as an exhibitor. Every application is subject to Exhibits Committee approval and no article can be exhibited unless it possess real merit.

For further information address

NATIONAL EXPOSITION OF POWER AND MECHANICAL ENGINEERING

Grand Central Palace, New York



Is YOUR Engine Sick?

Many an engine that keeps on running day after day ought to be on the "sick list." Because you can't see engine troubles you don't realize they are there and you continue to use more steam than is necessary, thereby wasting coal.

To get an accurate line on the condition of your engine—to learn whether it is pounding itself into premature old age—test it frequently with that infallible instrument, the

AMERICAN
THOMPSON
IMPROVED INDICATOR

You run your engine on a scientific basis when you own an American Indicator. It enables you to get the most out of your engine—to conserve steam and fuel—to detect leakage and losses of power—to correct internal troubles before they become serious—to produce a given horse-power on a minimum of coal.

It's as easy as ABC to use an American Indicator. No other indicator is so simple, so accurate, so up-to-date. Fitted with new Detent Motion, an exclusive feature, which permits the rapid changing of cards without unhooking cord.

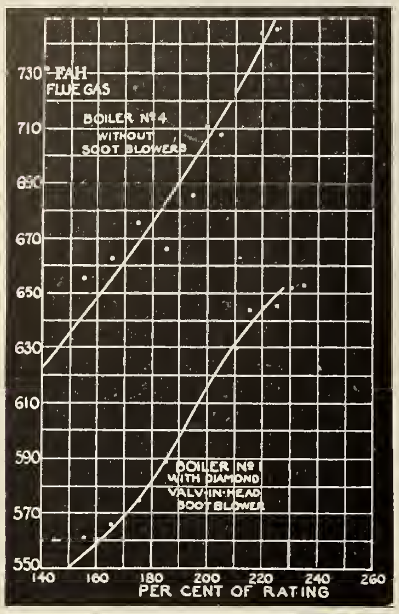
Diamond Soot Blowers Save Fuel at all ratings



This test was conducted on two duplicate 1000 h.p. horizontal water tube boilers, 170 lb. pressure, burning anthracite coal.

The lower curve covers the performance of boiler No. 1, fitted with Diamond "Valv-in-Head" soot blowers. The soot blowers were operated once every eight hours. Boiler No. 4, covered by the upper curve, was hand-cleaned once a week by means of an air hose.

The points plotted are reasonably consistent, and show an average gain of 90 degrees in favor of the "Valv-in-Head" soot blowers as compared to the air-cleaning. A 90 degree decrease in flue temperature at say 12 per cent. CO_2, represents a saving of 3.5 per cent. in carbon or about 3.1 per cent. in combustible.

An equipment, costing no more than Diamond Soot Blowers do, and which effects such savings in fuel, is an investment of the very first order. Diamond Soot Blowers pay for themselves many times over during their period of service.

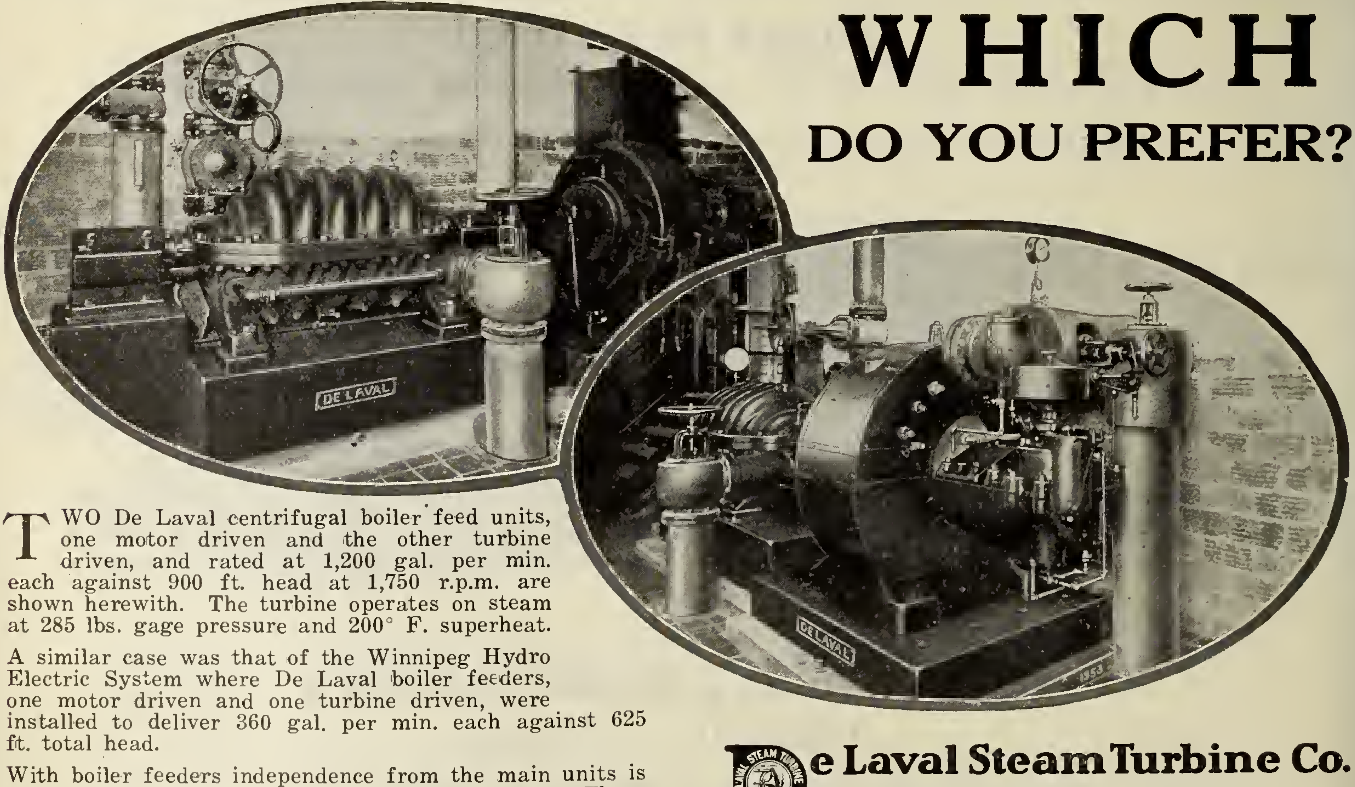
WHICH
DO YOU PREFER?



TWO De Laval centrifugal boiler feed units, one motor driven and the other turbine driven, and rated at 1,200 gal. per min. each against 900 ft. head at 1,750 r.p.m. are shown herewith. The turbine operates on steam at 285 lbs. gage pressure and 200° F. superheat.

A similar case was that of the Winnipeg Hydro Electric System where De Laval boiler feeders, one motor driven and one turbine driven, were installed to deliver 360 gal. per min. each against 625 ft. total head.

With boiler feeders independence from the main units is a strong argument for using steam turbine drive. There is no denying, however, that motor drive gives higher theoretical station efficiency, especially if the feed water is heated by steam bled from the main unit. For this reason De Laval centrifugal boiler feed pumps driven by electric motors were installed under the same capacity, head and speed conditions as the turbine driven boiler feed pumps.

Here is a modern school building where every provision is made to assure the comfort of the pupils.

Realizing what an important part dependable valve equipment plays in providing this comfort, it was decided to install only genuine Jenkins Diamond-marked Valves throughout the entire building. Both architects and engineers have pinned their faith to Jenkins Valves knowing that the Jenkins line assures lasting trouble-free service.

This confidence in Jenkins dependability is further proof of the fact that men whose knowledge of valve values is based upon practical experience recognize the name Jenkins as a guarantee of satisfaction.

Jenkins Valves are made in a big range of types and sizes for requirements of Power Plant, Plumbing and Heating service. Catalog No. 9 shows the complete line. Write for free copy.

Where you can get Plibrico!

SOMETIMES when furnace linings are needed, they're needed quick. Then it is that the engineer is glad that Plibrico—the one-piece lining—can be had from warehouse stocks close to him, where ever he is. In Canada a 'phone call, wire or letter will start Plibrico on the way if addressed to:

Montreal—Beveridge Supply Co.
Toronto—Shell, Bar, Boico Supply Co.
Vancouver—Evans, Coleman & Evans.
Winnipeg—Winnipeg Supply & Fuel Co.
Saskatoon—Building Products & Fuel, Ltd.
Regina—Dominion Lime & Coal Co.

When you need furnace linings in a hurry order Plibrico—you'll get long life in addition to speed of delivery.

PLIBRICO
FURNACE LINING
JOINTLESS FIRE BRICK CO.
1142 CLAY ST. CHICAGO

Plibrico is delivered only in steel containers of distinctive appearance, as shown above.

Use Logic in Buying Your Babbitt Metal

Protection from power waste, hot boxes and complete bearing breakdowns involves no particular increase in initial cost if you line your bearings with Magnolia Anti-Friction Metal, but you would effect a substantial ultimate saving, to say nothing of the more dependable service and relief from bearing worries.

If your supply man offers a substitute, write us direct.

Interior of the storage room of the Denver Ice and Cold Storage Company, Denver, Colo., showing Armstrong's Mastic Finish on Nonpareil Corkboard

No Other Finish Necessary

NONPAREIL Corkboard with 1/8-inch coating of Armstrong's Mastic Finish needs no plaster. The unbroken, impervious sheathing is perfect and permanent protection.

Armstrong's Mastic Finish is a waterproof mineral rubber compound, not mopped on the job, but ironed on Nonpareil Corkboard at the factory. It is keyed into the surface under pressure. Hot irons press out all bubbles and airholes. Armstrong's Mastic Finish does not soften at ordinary temperatures. It does not crack when cold. It has no odor.

The V-shaped joints are easily filled with a plastic compound which, when ironed, amalgamates with the mastic on the corkboard. There are no breaks between the boards.

In ice storages, coil lofts, hardening rooms and in all cold storage rooms where there is much moisture, Armstrong's Mastic Finish is recommended.

Full information will be furnished and a sample of Armstrong's Mastic Finish on Nonpareil Corkboard sent on request.

Class "PRS" Steam Driven Compressors

To meet the demand for a high grade steam Driven Compressor of larger capacity than our Class "FR-1" Straight-line type, we have designed the Class "PRS" Duplex Steam Driven Units shown above.

These machines are of enclosed construction with automatic lubrication. Frames, running parts, lubrication system and plate valve air-ends are identical with those used on our well known Class "PRB" and "PRE" belt and motor driven units.

Steam-ends are simple or compounded and are equipped with Ingersoll-Rand Balanced Piston Valves. These valves are very efficient and have much longer life than any other types.

Speed and Pressure Governing Devices or a combination of Speed and Pressure Governor and our Free Air Unloader can be furnished as desired.

Class "PRS" Compressors are suitable for mines, construction jobs or industrial plants where steam is used. They may be readily converted to power drive and are thus adapted for use where hydro-electric plants are under construction or where a combination of steam and motor drive is desirable.

Gasoline as a Refrigerant

THE conclusion reached by L. D. Wyant of the U. S. Bureau of Mines, after lengthy research, that gasoline is a convenient, economical and useful refrigerating medium, will prove unintelligible to the Canadian engineer.

From a careful examination of the report all that seems to be presented is the fact that gasoline can be used as a medium to which heat may be given at low temperature planes, and added to at progressively higher planes, by the heat equivalent of power and the sum total of heat added at both points may be used for heating a quantity of water at convenient planes of temperature.

This fact is merely a statement of general laws of thermodynamics that have been established for more than a century.

From the data given no one can tell whether the horse power per ton of refrigeration, when taking and discharging heat at certain planes, is more or less than with other fluids nor whether the displacement per unit of refrigeration, and hence the speed and size of the cylinders, will have to be greater or less than with other fluids.

Further, no information is given as to the boiling point of the liquid at different temperatures, the heat of the liquid, or the volume of the gas at different pressures. Without such data it is impossible to judge of its value, except perhaps to fall back on the general proposition that between the same temperatures, of reception and discharge of heat, the horse power is nearly the same for all fluids, barring incidental circumstances connected with their use. There is nothing in the report that throws any light on this subject and absolutely no data as to the practical volume and, therefore, design for a certain duty, or the horse power per ton.

The impression conveyed is that gasoline, as the motorist knows it ordinarily, was used, but although the specific gravity of the sample is given and the words volatile gasoline are used, there is indication that some hydrocarbon of lower boiling point than what we ordinarily call gasoline was used in the experiment, and perhaps a compound containing gasoline as a base having in solution many of the lighter hydrocarbons.

Men Who Are Busy

BUSY men—men who are really busy—always find time to do the things they should do. If you want something done, ask a busy man to do it. The men who are following the Hubbard articles—who are staying up half the night studying Watson's Easy Lessons—they are busy men—and to use the words of a prominent stoker manufacturer the other day: "Because they keep still, and you seldom or never hear from them, is no sign that they do not appreciate the many instructive articles contained in each issue of Power House."

Just the same, it's fine to hear from those who don't always keep still, for at no time has full credit been given those engineers who have worked out our modern comforts and well-being through the medium of the power house. Of all things in the scientific world, the furnace is the one that is most hidden, yet it is the origin of the great power that makes life in Canada what it is to-day.

It is not in the boiler nor in the machinery nor in the electricity that is generated. The combustion of coal is the main source that we have for living in this most comfortable of all ages—1923.

* * * *

Innovations in Design

IN THE consideration of any problem connected with the generation of steam power to-day, it must be remembered that we are in the early stages of a new era in the design of plants using coal as a fuel. The outstanding innovations confronting engineers, may be safely summarized in three groups, such as, more economical combustion of fuel; more economical generation and delivery of steam; and better utilization of the steam.

In the first group, one of the notable projects of the year in Canada has been the impetus given the burning of fuel in pulverized form, by material evidence of Henry Ford's project "to burn coal twice" in a $500,000 plant at Ford. The new process is based upon a method of coal distillation, which differs from all previous practice, in that the coal is distilled at a comparatively low temperature, making possible the recovery of "volatiles" which have hitherto been lost.

In the second group of innovations, must be noted the tendency to instal incline tube boilers, some only 9 tubes high, and up to 24 tubes high, varying in length from 18 to 25 feet. Superheaters also have been installed in various localities with wide differences in design. Economizers have been changed considerably in design and materials and in the treating and heating of boiler feed water, including condensate, long neglected, substantial progress is now being made.

The third group of innovations, embodying the utilization of steam, are those concerned with the so-called higher steam pressure of 400 and 550 lb., requiring smaller tube diameters and different design of boilers than for pressures under 385 lb. Extra high pressures of 1200 lb. naturally require heroic departures in boiler design of turbines, accessories, piping, boiler feed pumps and other equipment.

* * * *

Keep B. T. U's in Your Pocket

THE average executive demands the power plant supply—necessary heat and power—at the lowest possible cost. Aside from paying the bills he is not interested, yet, how many engineers, in recommending the purchase of new equipment, cite the B.t.u.'s that will be saved per hour and the increase in thermal efficiency such equipment will effect?

Wouldn't it be better for the engineer in giving the reasons for his purchases to keep the B.t.u.'s and efficiencies in his pocket and submit instead a reliable estimate of the savings in dollars and cents he hopes to effect?

His approach might be: "As an engineer, I know what I am talking about when I tell you these improvements will cost you——dollars and from them you will get a net return of——dollars a year."

Here in substance, is the kind of an approach that will get the attention and support of the busy executive.

Power—Their All!

POWER is a blessing to all its possessors,
Givers, receivers, and mediums, too,
Cherished alike by both clowns and professors,
Cause of our joys whether many or few.

Power is the life of the worst and the best of us,
Over us, under us, in and around,
Power to the north of us, south, east, and west of us,
Power in the water, the air, and the ground.

Dynamo, motor, train, boat, plane, or auto,
Man, beast, or bird, or the creatures that crawl,
Sun, wind, or river, they follow one motto,
Power is their pulses, their passion, their all.

Whether in pipe, cable, shaft, or conductor,
Power is the purpose and power the desire,
Power is our slave and our boss and instructor.
Light, heat, and power in eternity's fire.

Coal, wood, and oil for the engine and boiler,
Tides for the burdens of harbor and shore,
Powers for reducing the load of the toiler,
Spreading his table and filling his store.

Power for the needle, the pen, and the shovel,
Power for the task which we ought to perform,
Power for all needs, both of palace and hovel,
Limitless power for the ages unborn.

Power in the lightning, the searchlight, and taper,
Power in the growth of a worldful of crops,
Power in the liquid, the solid, the vapor,
Power in the atoms, the flakes, and the drops.

Power in the spring-time, and power in the autumn,
Power in the swing and the tilt of the earth,
Sweeping its map from the top to the bottom,
Fully conserved in a yearly rebirth.

Power beyond language, or figures, or measures,
Power omnipresent, omnipotent, free,
Bidding mankind to its store-house of treasures,
Manifold riches, conscripted would be.

Don't Treat a Lump of Coal With Contempt!

By K. L. DAWSON, Assistant Superintendent Gas Department, Nova Scotia Tramways & Power Company

An Increase of 10 Per Cent. in the Overall Efficiency of 95 Per Cent. of the Power Plants in the Dominion Would Cut the National Coal Bill $9,000,000 a Year

THE average person considers a lump of coal simply a convenient source of the heat which he finds necessary for the cooking of his food or the warming of his home.

He is so familiar with coal that he treats it with contempt, except perhaps when he comes to pay for it; then he transfers his contempt with his cheque to the party from whom he purchased it. He fails to see that the rising price is an indication of the approaching exhaustion of the beds from which coal can be easily mined and a warning that he should cease its indiscriminate destruction.

Coal is so much a part of our life that we all know something about it. We know there are different kinds; some of which break easily, others do not; some kindle easily, others do not; some burn with little smoke, others with much smoke. A few people have searched for the reasons behind these phenomena and have found that coal is a complex mineral containing many things, not the least wonderful of which are the liquids which are the basis of coal-tar dyes comprising 397 colors and shades.

Deplores Waste

This article is compiled for the purpose of illuminating the relationship of some physical and chemical facts as to the combustion and commercial distillation of coal and the preparation and use of some of its products. Incidentally, references will be made to the wastefulness of common methods of obtaining useful heat from raw coal.

When it was learned that coal was a better fuel than wood from the consumption of insignificant quantities, picked up on the earth's surface, man's ingenuity and mechanical ability were called upon to provide means whereby it could be brought from the depths of the earth.

In most mines it happens that coal occurs in several strata separated by layers of rocky material and it becomes necessary to excavate complicated systems of shafts and tunnels. Once reached, the coal may be mined by the pick and shovel or by machinery operated by electricity or compressed air.

Let us meet a "Lump of Coal" at the pit head and accompany it through a few vicissitudes to its ultimate destiny as a heat, light and power derivative.

Consumption Seasonal

The natural surroundings, and the methods used for mining it, demand that coal be produced at a more or less constant rate for maximum quantity and minimum price. At the same time its consumption is subject to seasonal demands.

In the spring and summer it cannot be sold as fast as it is produced and in the fall and winter it cannot be produced as fast as it is sold. Therefore, it is necessary for the producer to store it during times of small demand at points from which it can be conveniently distributed during times of maximum demand.

Those who have the facilities of space and cash for doing so usually purchase a yearly supply during the season of small demand when prices are easier, deliveries more prompt and quality more stable.

Journey to Pile

Suppose a group of us are interested in the purchase of a large quantity of coal. For the purpose of sampling it, we journey to the pile. Let us choose a lump from near the edge. If we closely examine it, turning it in our hand slowly to permit the light to fall on it from different angles, we shall see that it is laminated and that certain parts shine more brightly than others.

You may not be able to exit your flue gases at a temperature of 350 deg. as some plants do, but you must not let them get away a single degree hotter than your equipment, coupled with your best obtainable operation, warrants. Seventy-five per cent. efficiency may be far beyond the possibility of your outfit, but if 68 per cent. is actually possible, then 65 per cent. is not good enough. If you are able by your ability to get the best results possible right where you are, and if you actually do it, then and only then have you mastered the secret that will fit you to undertake a bigger job in a better equipped plant.

A pile of coal is not uniform. If it is formed by dumping from a trestle the larger lumps will be at the edges and the smallest at the top. An average sample must therefore be a fairly large quantity made up of smaller quantities, preferably equal in size, selected from the accessible portion of the pile at points separated by approximately equal distances.

This sample should be taken to a clean concrete floor and thoroughly mixed. It is then reduced in quantity by successive quarterings and in size of aggregate by pounding between quarterings, until a quantity and size are obtained which are suitable for the laboratory. After reaching the laboratory and undergoing grinding and further quartering with screening it is ready for chemical analysis.

Definite Information

In our endeavor to get definite chemical information we might try the method of preferential solution, on the same principle that a mixture of brick dust and common salt can be separated by dissolving the salt in water. By treating powdered coal with a suitable solvent we can separate it into two parts—one soluble in the solvent and the other insoluble.

This method has its difficulties. Ordinary solvents, such as ether and benzene, will dissolve very little of the coal substance. Stronger solvents may effect more or less decomposition in addition to, or without any, extraction. Therefore, in examining the extract and residue from strong solvents we must not assume that we are dealing with unchanged material.

If we have several weeks available we can attempt a slow distillation of the coal, raising the temperature of the sample so slowly that its every constituent will boil over at its proper boiling point and be entirely distilled over, as far as it will distil, before the temperature goes higher.

For the proper pursuit of this method we need equipment of larger than laboratory size, because some of the constituents of coal are present in very small quantities. If toluene is one per cent. of tar which in turn is five per cent. of coal by weight then the quantity of toluene to be found in a gram sample of coal would be infinitesimal.

Comparing the Results

Now suppose we take a portion of our sample and heat it quickly to 400°C., collecting the products and examining them; then we take a second portion and heat it to 600°C., again collecting and examining the products, repeating the process with other portions at 800°C. and 1,000°C. By comparison of the results obtained at one temperature and another, we shall derive useful information, although there can be no pretense of having obtained primary products of decomposition.

Next we may take a sample of suitable size and determine the elements from which the compounds in the coal are built up. The results of this process, expressed in percentages, are termed the "ultimate analysis" of the coal and will show the relationship of carbon, hydrogen, nitrogen, oxygen, sulphur, and ash to the whole. By further analysis of the ash we can determine whether or not the coal contains minerals which will make it unsuitable for boiler or other use or will cause clinkering.

Having accomplished these tests to our satisfaction, we shall probably agree with those who have made such tests before us, that coal consists of three groups of substances which may for convenience be termed celluloses, resins and the degraded products of nitrogen proteins. We shall also recognize that there is a definite relation which must exist between the celluloses and resins before a coal or mixture of coals will be suitable for distillation on a commercial scale with marketable products.

Proximate Analysis

There is a last treatment which we may give a portion of our sample. In commerce it is the most widely known analysis of coal and is called the "Proximate Analysis." By it we can determine quickly the quantity of moisture, volatile matter, fixed carbon and ash in our sample.

After making the volatile test by heating a gram sample in a crucible, with a snug cover, over the flame of a Meker burner for seven minutes, a cake will remain. The appearance of this cake will generally provide the answer to the question of the suitability of our coal for commercial distillation.

The cake is known as "coke." A hard coke of silvery lustre indicates a sufficiency of resin, a powdery coke indicates almost absence and a weak black coke indicates insufficiency.

Suppose that the results of all our analyses show the coal to be suitable for our purposes and we order the pile shipped to our plant.

Coal, after some weeks of exposure to the air and sun is liable to take fire. Coal stored in a building is also liable to take fire. What then is the best way in which to store coal?

Storage under water, out of contact with the air, is undoubtedly the best means of preserving coal, and one which has been adopted in some places on a large scale. While the elimination of any risk of fire is obvious, it is not to be assumed that the coal suffers no alteration in these conditions. Analyses show a slight loss of calorific power in coal so treated.

There is in fact a slow oxidation by oxygen dissolved in the water, and also solution of the gases occluded in the coal. The loss may, however, be considered negligible in comparison with the advantages secured. Nevertheless the cost of reservoirs and conveying gear, and the necessity of handling coal in the wet state are considerations which militate decisively against adoption of the system.

Storage in Buildings

Concerning storage in buildings recent experiments made by M. Forrieres, in France, are interesting. This scientist designed three covered coal-stores. One of these had brick walls on three sides, but was open along one of the short sides. The other two had only two walls at right angles—the roofing being supported by brickwork pillars on the open sides.

The first thing which was noticed was that no fire or overheating developed in the first of these stores. On the other hand, every case of incipient fire in the other stores originated not to the rear near the walls, but always near the outside, from nine to sixteen feet from the open side. The coal was about 25 per cent. broken and the height of the stack eleven feet. Evidently there are limits to the quantity and condition of air which is favorable to spontaneous combustion.

Storage in the open is best accomplished when the piles are not more than six to eight feet deep and limited in area so that all parts are readily accessible for the detection of overheating.

There are several things which contribute to the spontaneous combustion of coal, chief of which is the oxidation of the coal substance itself on exposure to the air. The presence of excess moisture and the oxidation of pyrites contained in the coal are secondary in importance. They seem to be assistants, rather than coworkers in that the moisture helps to distribute the heat generated by the oxidation of the coal substance, while the oxidation of the pyrites, although productive of some heat, serves to disintegrate the coal, thereby exposing a larger area of its surface to oxidation.

Power House travels far with its message of economy and its ideas for better methods, and it serves broadly every industry that exists, for it serves a profession that is basic and a group of men universally needed in the industrial scheme of things. Their number is small, but the power they wield is great, for the combustion problems of all industries offer in their solution a tremendous opportunity for both those who supply brains, and those who supply equipment, doubly for those who supply both.

Lignites Oxidizable

It has long been recognized that there is no close relation between the proximate and ultimate analyses of coal and its liability to spontaneous combustion. Coals of different classes may be differentiated, however; the ease of ignition decreasing with the degree of "carbonization" of the coal. Thus lignites are the most easily oxidizable, then follow the various grades of bituminous coals, the steam coals and anthracites.

Let us turn our attention now for a little while to the use of coal for the purposes of the home and the power plant.

Recently David Brownlie divided the steam-raising plants in the United Kingdom into three classes to each of which he gave efficiency ratings for water tube and fire tube boilers as follows:

Percentage of whole	Class	Efficiency Rating Water Tube	Efficiency Rating Fire Tube
10%	Bad	61%	49%
85%	Average	69%	60%
5%	Highly Efficient	83%	79%

Probably the percentage in the first column can be applied to Canadian steam plants, although I have heard it said that the average efficiency of North American steam plants was higher than the average of the United Kingdom, but I have never seen figures to prove the contention. On the whole it will probably be agreed that the efficiency of steam plants with the exception of five per cent. which are already highly efficient, can and should be improved as a matter of national importance.

A Public Nuisance

The use of coal for domestic purposes and in inefficient steam plants gives rise to a public nuisance, which has grown in some places to such an extent that statutes have been passed which tend to its abatement. I refer to the smoke nuisance.

In Glasgow investigators have proved that the deposits of carbonaceous matter are heaviest in the residential and office-building sections of the City. The formation of smoke is wasteful. Smoke abatement practically always results in fuel conservation, usually not less than 10 per cent. and frequently 20 to 30 per cent.

It is estimated that smoke costs every man, woman and child in the Pittsburgh district $20.00 per year. This is the cost of extra laundry work, for paint to renovate smoked walls and woodwork, and for cleaning and materials for this purpose, without consideration of the matter of health.

It is probably ultraconservative to state that the damage per ton of bituminous coal burned in a city having a fair degree of smoke abatement is not less than $1.00 per ton of coal consumed, and that the loss per head is not under $8.00 per annum.

Combustion Problems

The cause of the production of smoke is wrapped up in the chemistry of the combustion of coal, of which time will permit no comprehensive speaking. Briefly, coal is a mixture of many compounds containing varying quantities of carbon and hydrogen. Some of these compounds are very unstable even at ordinary temperatures. Some are readily gasified and others cannot be gasified except at high temperatures. Although combination with oxygen at high temperatures appears to take place in a simple manner, this is really not the case.

It has been shown that, when combustion proceeds at low temperatures in the presence of a catalyst, many intermediate products are formed before the final products, carbon dioxide and water vapor, emerge. Thus during the slow combustion at 400°C of the simple hydro-carbon ethane, products such as ethyl, alcohol, glycol, acetaldehyde, formaldehyde, and formic acid are formed before the final production of carbon dioxide and water vapor. Oxygen enters the molecule at several definite stages involving the successive formation of the products mentioned above. Therefore the apparent simplicity of the reactions involved in the combustion of simple gaseous hydrocarbons is due to their high velocity at high temperatures.

The combustion of the more complex hydrocarbon molecules has not yet been studied in the manner described above, but it is easy to imagine that, as the hydrocarbon molecules increase in their complexity, so the number and variety of intermediate stages in the oxidation process will increase, and that a culminating point will be reached when the formation of intermediate products cannot be masked by the high velocity of reaction. The result is a tendency to incomplete combustion.

Complexity of Reactions

In the case of the combustion of raw coal, the complexity of the reactions which take place during oxidation is augmented by a number of side reactions of a physical as well as a chemical nature. The process is preceded and accompanied by the decomposition of the coal substance.

Long before the ignition temperature has been reached—which for the purposes of discussion may be regarded as the temperature at which active oxidation occurs—some of the coal substance melts or decomposes into less complex bodies, and frequently with the evolution of gas, while the newly formed degradation products may also melt and further decompose.

If the boiling point of any of these liquids is lower than the temperature of decomposition distillation will immediately take place; and if the vapors come into contact with a cooler zone, condensation and smoke formation will result. The gas may, however, become heated in the course of its passage, so that ignition takes place; but it is impossible to predict the sequence of events, as it is impossible to control the conditions to which the products of combustion will be subjected. There is no doubt that the coal substance undergoes extensive decomposition, either in the solid or liquid form, prior to distillation.

Whether the distillation products ignite or escape as smoke would appear to depend upon the relation between the ignition temperature and the boiling point. Where there is a large temperature difference there is obviously greater opportunity for the gas to be carried away into a cooler zone before combustion occurs.

Preheated Air

Another factor to be considered in the production of smoke is the fact that it is usually evolved in a zone already highly charged with the products of combustion. For this reason, a suitable excess of air must be provided; and if such air is admitted to the combustion chamber above the level of the fire it must be preheated to avoid cooling the smoke below the ignition temperature.

The use of raw coal is deprecated owing to the impossibility of controlling the combustion process. The lack of control results in either the production of smoke or the use of a large excess of air, both of which represent the loss of energy.

Finally, the combustion of raw coal represents to the chemist an appalling waste of chemical products, such as ammonia, sulphur, cyanogen and coal tar derivatives; the latter being those products on which we must depend in Canada for building up an organic chemical industry to successfully resist foreign competition.

If a thimbleful of powdered coal is heated in an open test-tube it will first send off little puffs of vapors which will condense further up. Further heating will drive off brownish fumes, some of which will float away and some condense until the test-tube is black. Stronger heating will drive away everything which will distill, leaving solids in the bottom and clinging to the sides.

Should all the fumes be caught in a large transparent jar it will be found that some will condense to form the brownish-black, viscous liquid known as tar. The water vapor which is not needed for saturation will condense and mix with or float on the tar. The remainder will be impure gas. The solids remaining in the test-tube make the substance known in the fuel trade as "coke."

Two Processes

Commercially this phenomenon is utilized in two high temperature processes, gas works and coke oven practices. The first aims to produce the best possible grade of gas for heating and lighting purposes, the second aims to produce the best possible coke for the purposes of the metal working industries.

In modern gas works construction the chamber or retort into which the coal is placed for treatment is more or less rectangular in cross-section. According to the position of its longitudinal axis it is known as a horizontal, inclined or vertical retort. It may be built to hold 300 pounds to 2,000 pounds of coal. Usually it is made up of carefully molded silica blocks, grooved and tongued to fit snugly together. Any small cracks fill with carbonaceous material the whole soon becoming tight.

In the ordinary manufacturing plant, only three per cent. of the heat energy in coal is effectively utilized. Think of this in relation to this year's coal consumption, and you will realize the enormous waste. Probably, fifty million dollars will be the price paid this year for inefficient combustion methods in Canada.

Because the heat which is applied to the exterior of the retort must penetrate through its walls into the heart of the coal mass inside, the walls are made as thin as possible, consistent with strength and the width of the retort is restricted to from 12 to 24 inches. The other dimensions of the cross-section may be, say 15" to 36". The length of the retort may be five feet to 20 feet or more, depending upon the position of the long axis or the methods employed for filling or emptying.

Doors are provided at one or both ends through which the coal is inserted and the residue removed and one or more openings through which the gas may escape.

Adjustment of Air

The heat to which the coal is subjected comes from a furnace below the retort in which is a bed of incandescent coke three to six feet deep.

The air for its combustion is admitted through a shutter, which can be readily and accurately adjusted. On its way to the underside of the grate it is conducted through passages heated externally by the waste gases on their way to the chimney. In these it is preheated and mixed with superheated steam.

The steam serves two purposes. It abates the evil formation of hard clinker and gives to the furnace the function of a gas producer. The gas from the top of the fire passes through nostrils upwards into the flues surrounding the retort. Here it meets a current of preheated secondary air and complete combustion is attained giving a higher temperature around the retort than is attained in the furnace which is just what is needed. In the gas works at Halifax the temperature in the furnace is between 1,800°F to 2,000°F; around the retorts 2,200-2,300°F.

The distillation by which coal is now being separated is a violent affair, much different to our laboratory distillations. The coal is placed in a retort already as hot as we expect to get it and therefore our distillation products are going to be entirely different from the original constituents of the coal.

After gasification the products are subjected to the decomposing influence of the red hot coke and the silica walls of the retort and their radiant heat. Also the atmosphere in the retort is continually changing and to a certain extent the pressure. These physical surroundings give rise to secondary chemical reactions which are of first order of importance. Without them benzol and toluol which are so important in the color industry would be produced in much smaller quantities.

Distribution of Heat

The temperature around the retort and the distribution of the heat along its surface must be capable of control and regulation. Precision instruments and properly placed dampers are in continuous use in an efficient plant. Too high temperatures cause the formation of lampblack and napthalene.

Lampblack is carried forward in the gaseous stream from the retort and mixing with the condensed tar gives rise to stoppage in gas and tar mains, which must be dug out. One can hardly visualize how tenaceous and rubbery a mixture of lampblack and tar can become until he opens a passage through a pipe which is stopped with it.

Napthalene will be carried forward into the distribution pipes where it will sublime in flakes like snow. As the pressure in these mains is usually small very little napthalene can produce a stoppage. If the temperature is too low not all the gaseous constituents will be removed from the coal and the residue will have a dirty appearance instead of the clean, silvery lustre which we are accustomed to see. Too high or too low temperatures will therefore result in decreased efficiency.

The gaseous mixture coming from the retorts is of course hot and requires cooling, a matter of equal importance with its production. Any method of reduction will not suffice. The reduction must take place in such a way that a maximum quantity of all the valuable constituents will be retained in the gas.

Describes Halifax Plant

Perhaps the best way to tell the various steps in the process of preparation through which coal gas must pass before it is marketable is to describe how it is done in a plant with which I am familiar.

In Halifax crude gas is drawn from the retorts through the primary condenser to the exhauster. The condenser is a vertical cylindrical tank containing a number of large tubes. Through the tubes a current of air is flowing upward under natural draft. The gas entering the condenser is forced to take a circuitous path back and forth around and between the tubes by baffles which are placed horizontally. As it passes, the liquid and solid matter is reduced by agglomeration and subsequent deposit in the same way as globules of water in a cloud produce rain. The change in direction and velocity of the gas caused by the baffles produces the necessary physical conditions. As this is going on the temperature is reduced under absolute control to a predetermined point.

The exhauster is a mechanical contrivance usually operated by a steam-engine which sucks the gas through all the apparatus preceding and pushes it through all the apparatus following it. The vaccum created on the suction side will support a column of water one inch high at the exhauster and two tenths of an inch high at the retort. The pressure in the main at the outlet of the exhauster will support a column of water about fourteen inches high.

Use Tar Extractor

The first piece of apparatus on the pressure side is the tar extractor. The gas enters an inner chamber of which the walls are made of several perforated plates, one outside the other. The perforations are so made and arranged that a row of pinholes in the inner plate will oppose a blank space on the plate next outside. Screening by and impact on the successive plates following change in velocity and direction of flow between the plates changes the vapors of tarry liquids into liquid tar which runs down the plates and is withdrawn through a seal.

Because tar vapor absorbs various undesirable constituents such as napthalene, its capacity increasing with the reduction of the temperature, it is allowed to remain with the gas to as low a temperature as may be for the purpose; but as it is also an absorbent for the hydrocarbons required for illuminating purposes, it must not be allowed to remain when the temperature falls so low that the illuminants will be removed to an injurious extent. The proper temperature as determined by numerous experiments is 90°F to 105°F.

In a plant sending out 300,000 cubic feet of gas per day the secondary condensation and cooling for the reduction of other vapors can usually be accomplished by a water-cooled condenser, similar in construction to the air cooled primary condenser, just described. Such vapors as will condense here will be deposited in very close accordance with their vapor tensions. As they deposit they are removed from contact with the gas to prevent their solution of vapors which it is desirable to retain.

Vapor of Napthalene

As an illustration of factors to be remembered in the design of this condenser consider the vapor of napthalene. At any temperature say 70°F, there will be a certain amount of napthalene vapor in the gas according to the vapor tension of napthalene at that temperature. Benzol will be present in a certain quantity due to its corresponding vapor tension. But as benzol is a solvent for napthalene it is found that the napthalene content in the presence of benzol may exceed the quantity corresponding to its simple vapor tension.

If the condensation and cooling is not done efficiently here then at some point further along some benzol may liquefy, freeing the napthalene it was carrying. This will cause a super-saturation of the napthalene followed by its deposit in the solid form.

The gas passes from the secondary condenser to the washer where its flow is broken into many minute streams which bubble upward through two or three inches of water.

The primary function of the washer is to remove the final traces of tarry matter and whatever dust may have remained in the gas to this point. It has however a secondary function which is due to the use of water in it. At the inlet of the washer the temperature of the gas is 50–70 degrees F. At this temperature the gas is ready for the removal of ammonia and hydrogen sulphide. Water readily absorbs ammonia, ammonia reacts slightly with hydrogen sulphide, therefore the washer removes a little of each.

The combustion engineer, operating engineer, and fireman who takes the time and trouble to educate himself to reduce the amount of coal consumed, and to produce steam at less cost, should receive the support of every power plant owner in the Dominion.

From the washer the gas is conducted to the bottom of a steel tower which contains layers of coke supported on perforated trays over which a small quantity of water is trickling.

As the gas passes upward it comes into intimate contact with the water exposed over the vast surface of the coke and a great proportion of the ammonia is absorbed by the water. The remainder is absorbed in a second tower to such an extent that a stream of gas impinging on moistened tumeric paper will cause no change of color.

Gas Contents of Coal

Gas from a good grade of United States gas-coal will contain from 200 to 500 grains of sulphuretted hydrogen per 100 cubic feet at this point. The gas from native coals contains 500 to 800 grains. Its removal in its entirety is comparatively simple.

When the gas is passed through layers of iron oxide such as bog iron ore, two to three feet deep, supported on perforated trays in suitable containers, the sulphuretted hydrogen is removed by a reaction which changes the oxide to the sulphide.

The purification of a daily output of 300,000 cubic feet of gas containing 700 grains of sulphuretted hydrogen per 100 feet means the removal of 300 pounds of hydrogen sulphide per day, four and one half tons per month. Under these conditions the oxide is rapidly sulphided until it must be removed and replaced. Up to a certain point the foul oxide will be revivified by exposure to the air, but repeated foulings will finally render it useless when it must be discarded in favor of fresh.

Gas from American coal will now contain 10–20 grains of organic sulphur per hundred cubic feet while gas from the best native coals which we have been able to obtain will contain from 50 to 70 grains.

The larger quantity is present in the form of the vapor of the extremely volatile carbon bisulphide and there is no simple way of removing it. One company accomplishes it by raising the gas to a high temperature, 500 degrees F., in the presence of iron oxide. The water vapor ordinarily carried in the gas augmented by the introduction of steam if necessary reacts, with the carbon disulphide and results in hydrogen sulphide and the oxides of carbon. The hydrogen sulphide may be removed by further contact of the gas with iron oxide.

Processes like these could not be considered for Halifax because of their high cost. Instead the gas is passed through a series of three towers in which a petroleum distillate known as pale paraffin oil is flowing downward through excelsior and wooden grids while the gas is passing upward.

Using about ten gallons of oil per 1,000 cubic feet of gas at a temperature slightly lower than that of the gas it is possible to accomplish the removal of 40 per cent. of the organic sulphur, which leaves a quantity entirely inoffensive when the gas is burned in properly vented appliances.

A good general rule is that all appliances consuming extensive oxygen should be vented. By heating the oil to 260 degrees F. the absorbed vapors are expelled. It is then ready for use again.

Residue in Retort

The residue left in the retort when the distillation has been carried as far as it is practicable is coke. Except in the case of some types of vertical retorts it is hot when withdrawn and has to be cooled by quenching or smothering. When crushed and sorted it is ready for marketing.

The hydrocarbons in the coal and the products which give rise to the smoke from an ordinary fire may be considered to comprise that portion of the coal from which gas and tar are obtained—the greater their quantity in the original coal or, technically speaking, the higher the volatility of the coal, the greater the volume of gas obtainable.

Whether or not marketable products may be obtained from the distillation of a given coal is usually inferable from its proximate analysis and the appearance of the residue left from the volatile test. A high percentage of volatile must be accompanied by a low percentage of ash and especially a low percentage of sulphur, and the qualities which will produce a clean coherent coke, not readily friable. Such coal is growing rarer and the price of what is now available is rising.

Dream of Paradise

It seems natural then for the gas men to dream of a paradise where any old kind of coal can be changed entirely into a marketable gas with no by-product except

(Turn to page 44)

Facts You Should Know About Steam Generation

*By CHARLES L. HUBBARD

Steam Simply a Convenient Medium for Carrying Heat From Boiler Furnace to Engine or Turbine Where a Portion is Transformed Into Work in the Ratio of 778 Foot-Pounds per B.T.U.

AS STEAM is so intimately connected with the subject of prime movers, and power plant equipment in general, it is well to dwell somewhat upon the principles involved in its generation before considering its transformation into work in engines and turbines.

Strictly speaking, it is the heat which it contains and not the steam itself, which produces mechanical energy. Steam is simply a convenient medium for carrying the heat from the boiler furnace to the engine or turbine, where a portion of it is transformed into work in the ratio of 778 foot-pounds per B.t.u.

There is probably nothing better than the old illustration of the closed cylinder and movable piston for showing what takes place in changing water into steam by the application of heat. The apparatus shown in Figure 1 consists of a vertical cylinder, open to the atmosphere, and provided with a tight-filling piston which moves easily within it.

Three Results Obtained

If a given quantity of water is introduced beneath the piston, a weight placed on top of it, and the gas jet beneath it lighted, three definite results will be observed as follows:

1. The temperature of the water will gradually rise until a point is reached where boiling takes place and steam begins to form. If the sectional area of the cylinder is 30 sq. in. and the weight of the loaded piston 150 pounds, so as to exert a gage pressure of 5 lbs. per sq. in. upon the surface of the water, boiling will take place at a temperature of 228 deg. F.

2. During the process of evaporation, the piston will rise to make room for the greater volume required by the steam; but although heat is constantly supplied the temperature will remain the same as when boiling first began (see Figure 2) and continue so until the water has all been changed into steam.

3. If, after evaporation has been completed, heat is still supplied, the piston will continue to rise, and the temperature increase, but the pressure remains constant as before, (see Figure 3).

Analyzing Phenomena

Let us now analyze these various phenomena, and see what has actually taken place.

1. The heat absorbed by the water in raising its temperature to the boiling point, under the given pressure, is called the "heat of the liquid." For the sake of uniformity, this is commonly measured from 32 deg., in the results given in "steam tables."

In the above example, the heat in the liquid would be measured from the initial temperature when the gas burner was lighted.

2. During the period of evaporation, the heat which disappeared was used in two ways, part, called the "internal latent heat," being absorbed in the work of changing the liquid to a gaseous form, and part, called the "external latent heat," in the work of expansion, and shown by the increase in volume in Fig. 2. The sum of these two is called the "latent heat of evaporation," and is given out again when the steam is condensed.

Steam Is "Saturated"

During the process of evaporation, and as long as any water remained in the bottom of the cylinder, the steam was what is known as "saturated." In the case of saturated steam there is always a definite relation between pressure and temperature.

In the illustration of the cylinder, the pressure was assumed to be 5 lbs. per sq. in., (above atmospheric pressure) in which case the temperature was 228 deg. If the pressure had been 10 lbs.. the temperature would have been 240 deg., and so on.

After the water in the cylinder was all evaporated, it was found that the continued application of heat increased the volume of the steam and raised its temperature, but did not affect the pressure as long as it was able to expand by raising the piston.

Steam in this condition is said to be "superheated," and the definite relation between pressure and temperature no longer exists. The heat contained in a pound of superheated steam is the same as that in a pound of saturated steam at the same pressure, plus that absorbed in the process of superheating. The heat of the liquid and the latent heat of evaporation are the same in each case, because the superheated steam has been produced from a pound of saturated steam by adding more heat.

ADVANTAGES OF SUPERHEATED STEAM

1. Ability to use smaller piping.
2. Steam separators are not required
3. Radiation losses are reduced.
4. So used in turbines superheated steam impinges against blades at higher velocity.
5. Absence of condensation in the pipe lines which results in (a) elimination of water hammer and (b) reduction in radiation losses.

Properties of Steam

The various properties of saturated steam at different pressure, are given in "steam tables," which are found in engineering handbooks and in many trade catalogs devoted to power plant equipment. In the latest books on steam engineering, the properties of superheated steam are also included.

In case a table of this kind is not at hand, and it is desired to find the total heat in a pound of steam containing a certain amount of superheat, the factors in Table 1 may be made use of in connection with an ordinary steam table.

TABLE I

Steam pressure (Gage)	Degrees of Superheat 60	100	150	200
85	0.546	0.534	0.522	0.515
110	0.565	0.548	0.534	0.524
135	0.585	0.562	0.544	0.533
185	0.623	0.590	0.563	0.548

Example—What is the total, heat above 32 deg., contained in a pound of steam at 135 lbs. pressure and having 150 deg. superheat? Also what would be its temperature?

From a table of the properties of saturated steam, we find for this pressure the total heat per pound to be 1,193.4 B.t.u. and the temperature 358.5 deg. The factor for 135 lbs. pressure and 150 deg. superheat is found from Table 1 to be 0.544, which gives a total heat for the superheated steam of 1.193 + (150 × 0.544) = 1,275 B.t.u. The temperature will evidently be 3.85 + 150 = 5.35.5 deg.

Saturated steam may be either dry or wet, the term "wet" denoting the presence of a certain amount of water in the form of a mist or priming. The percentage of dry vapor in steam containing moisture (wet steam) is called the quality, that is, steam containing 3% of spray or mist would have a quality of 100 — 3 = 97%.

Superheated Steam Dry

Superheated steam, from its nature, is always dry. Saturated steam supplied to an engine or turbine should always be passed through a separator to remove the moisture before it is delivered to the machine, as its presence lowers the efficiency. Spray or priming

in considerable quantities may do serious damage, both to engines and turbines.

As superheated steam has come into quite general use during recent years, it may be well to devote a little time to a discussion of its advantages, its limitations, and matters to be considered in its practical application to the generation of power in engines and turbines.

It is a well-known fact that the greatest waste of heat in a steam engine, aside from that carried away in the exhaust, is that due to cylinder condensation. When saturated steam enters the cylinder, a large percentage is at once condensed by contact with the cool walls, which are at approximately the temperature of the exhaust which has just been expelled. After the point of cut-off, the pressure, and consequently the temperature fall, due to expansion, and condensation still continues through in a lesser degree, until a point is reached where the temperature of the steam and that of the cylinder walls are the same, at which time condensation ceases.

Will Return Heat

From this point to the end of the stroke the walls will return a certain amount of heat to the steam, causing a part of the moisture to be re-evaporated. This process, however, returns only a small part of the moisture to a gaseous form, as the greater part of the heat is given back from the cylinder walls during the period of exhaust, and is, therefore, wasted, so far as doing useful work in the cylinder is concerned.

When superheated steam is employed, no condensation can take place until sufficient heat has been extracted to reduce its temperature to a point corresponding with that of saturated steam at the same pressure. It is common practice to superheat the steam just enough to supply the necessary heat transfer to the cylinder walls up to the point of cut-off, thus doing away with initial condensation entirely.

Beyond Cut-Off Point

While it is true that heat is lost in this case, the same as though condensation took place, the quantity is greatly reduced. Beyond the point of cut-off the steam is saturated, and sufficient condensation takes place to moisten the cylinder walls and thus assist in proper lubrication.

The amount of superheat required will depend somewhat upon the initial pressure of the steam, the ratio of expansion, and so forth, and in general will vary between 100 and 300 deg. The earlier the cut-off, the higher the degree of superheat required, so that the process is limited to some extent because it is not practicable to exceed a temperature of about 500 deg. with the form of valve construction commonly employed.'

Under average conditions, 150 deg. of superheat has been found to give very satisfactory results in practice, which, in case of steam at 150 lbs. gage pressure, would give a maximum temperature of 350 + 150 = 500 deg. The actual reduction in cylinder condensation, under the general conditions of practical operation will amount to 1% for each 8 to 10 deg. of superheat.

Again in Volume

Another advantage to be derived from superheating is a reduction in the weight of steam used per stroke for a given amount of work. For example, saturated steam at a gage pressure of 125 pounds, has a total heat of 1,192 B.t.u. per lb. above 32 deg., and a volume of 3.22 cubic ft. Adding 150 deg. of superheat increases the volume to 4.10 cubic ft. at the same pressure and requires 81 B.t.u. Here we have a gain in volume of $\frac{4.10}{3.22} = 1{,}242$ or 24.2%, with an increase in heat expenditure of only $\frac{1.192+81}{1.192} = 1.068$ or 6.8%.

Increase in volume at constant pressure means a gain in power for a given water-rate, or a reduction in water-rate for a given power of engine. While the above figures are theoretical they show the general effect of superheating as regards economy of operation.

Although both theoretical computations and actual tests show a reduction in steam consumption in favor of superheated as against saturated steam, for a wide range of conditions, the actual saving must take into account cost of equipment, depreciation, operation, and so on, which makes a wide variation and sometimes reverses the results.

Various Figures Given

Various figures are given for the saving in steam consumption with superheating, and run from 10 to 20%. Gebhout gives 20% for simple noncondensing engines with medium piston speed; and 10% for compound condensing Corliss engines, with 100 to 125 deg. of superheat, and continuous operation. Simpson gives an average of 15% for engines of 250 to 500 horsepower, with the same range of superheating as above. St. Cyr gives 10% for steam turbines, 15% for compound engines, and 20% for simple engines with 100 deg. of superheat in each case.

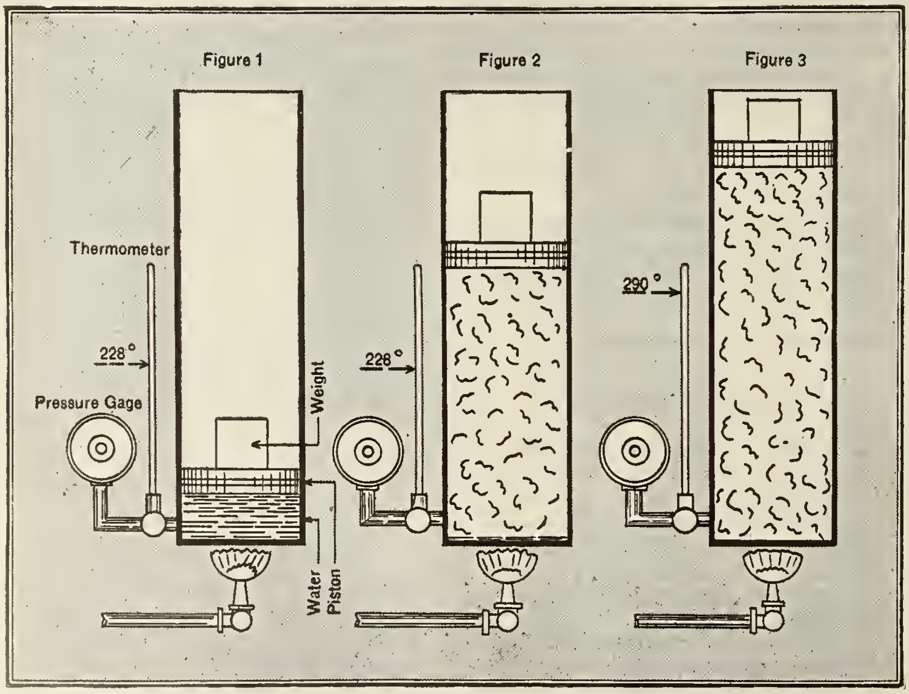
While a saving in weight of steam per unit of power developed by the engine may be obtained by superheating, it does not follow that the saving in fuel is in the same proportion, because the total heat contained in a pound of superheated steam at a given pressure is greater than that in a pound of saturated steam at the same pressure.

This may be illustrated as follows: Suppose, in a given case, the steam consumption of an engine operating at 125 lbs. gage pressure, with saturated steam, is reduced 20% by superheating 150 deg. That is, for every pound of steam required in the first case only 0.8 pounds will be used in the second.

One pound of saturated steam at 125 lbs. gage pressure contains 1,192 B.t.u. above 32 deg., and 0.8 lbs. of steam at the same pressure, superheated to 150 deg., contains (1,192 + 81) × 0.8 = 1,018 B.t.u., or 1,192 — 1,018 = 174 B.t.u. less, and is capable of doing the same amount of work.

That is, a reduction of 20% in steam consumption produces, under the above conditions, only $\frac{174}{1{,}192} = 0.146$ or 14.6% reduction in the amount of heat required of the boiler. When computing, the ultimate saving by superheating, this fact must be taken into account as well as the interest and depreciation charges on the superheater.

On the other hand, a saving of 20% in steam consumption for a given



Figures 1, 2, and 3: One of the simplest methods of illustrating the amount of heat stored in steam which can be converted into useful mechanical work is that of the closed cylinder with a movable piston.

amount of power means a corresponding reduction in boiler capacity, which is an important item in the construction of a new plant or the extension of an old one.

If four boilers may be made to do the work of five, the omission of the extra unit would probably cover the cost of the superheating equipment, so that in certain cases the full saving in fuel, as computed above, might be realized.

In making estimates for increased economy, the total number of hours per year at which the plant is operated should be taken into account, as the load factor is an important matter in determining the advisability of installing superheaters as well as other forms of power plant equipment.

In a general way, superheaters should affect a net saving equivalent to about 10% on the first cost, above depreciation and maintenance charges, to warrant their installation in the average case.

Distortion of Gear

The degree of superheat which it is practicable to employ is limited by difficulties experienced in lubrication and in the distortion of certain forms of valve gear under excessively high temperatures. A maximum steam temperature of 500 deg. is about the limit for reciprocating engines, and corresponds to 175 deg. of superheat at 100 lbs. pressure, and 125 deg. at 200 lbs. The obstacles to high temperatures have been overcome to some extent by the introduction of special lubricating oils and devices for suitably atomizing it. Piston and poppet valves give especially good results under high temperatures and are being used to a considerable extent in the latest types of engines.

Steam turbines require no lubrication inside the steam chambers, and from their mechanical construction are not so liable to distortion as the valves of reciprocating engines.

Advantages Marked

The advantage of superheated steam in connection with the turbine is especially marked. Although the item of condensation is small in this case, because the surfaces in contact with the steam are always at practically the same temperature, there are other advantages equally important, among which may be mentioned the higher velocity with which superheated steam will impinge against the blades. Experiments have shown a saving of 10 to 12% when the steam is superheated.

This advantage, however, is limited to new plants, as there would be nothing gained in taking down piping already installed for the sake of using smaller sizes for the same work. In new plants there will be a substantial saving, as the cost of pipe, filling, and valves increases rapidly with any increase in size, and especially with material of the comparatively large size employed in power plant work.

Another advantage is the absence of condensation in the pipe lines, as there can be no moisture in the steam until it falls below the point of saturation. This is desirable both on account of the elimination of water hammer and the reduction in radiation losses, as previously stated. In various processes involving the use of steam it has been found advantageous to add a certain amount of superheat in a variety of cases, as in kettles, dryers, stills, and so on, regardless of whether jackets and coils are employed or the steam mixed directly with the substance to be heated.

Suitable for Strain

A matter which must be carefully looked into when changing over from saturated to superheated steam is whether the existing pipes and fittings are suitable for withstanding the higher temperature and the greater expansion strains resulting.

In new work steel fittings are recommended, or if cast iron is used, the metal should be low in silicon and high in steel so as to give the greatest degree of toughness possible. Many plants are running at the present time with steam superheated to a moderate degree and employing piping systems made up with cast-iron fittings, and have given satisfaction through many years of service. Much depends, however, upon the quality of the iron and the arrangement of the pipe lines for taking up the expansion.

Now let us consider briefly tests and measurements. Steam is tested for quality by means of an instrument called a "calorimeter." These are of two kinds, the "throttling" and "separating." The first is adapted to cases where the amount of moisture in the steam is small. The limits are about 3% at 80 lbs. gage pressure and 5% at 200 lbs. pressure.

The general construction of a throttling calorimeter is shown in Figure 4. Steam entering from the main pipe strikes thermometer No. 1, which indicates its temperature, and from which the corresponding pressure may be obtained from a steam table.

It then passes through a small orifice (a) into a chamber (b) which is under atmospheric pressure. As the total heat in a pound of steam is greater at the higher boiler pressure than at atmospheric pressure, a certain amount of heat is liberated in the process of expansion in chamber (b), and the steam becomes superheated, and the thermometer No. 2 will register a higher temperature than that corresponding to saturated steam at atmospheric pressure.

The formula for determining the quality of steam with a throttling calorimeter is

$$x = \frac{r_2 + q_2 + 0.47\,(ts - t_2) - q_1}{r_1}$$

in which X = quality of the steam.

r_2 = latent heat of steam at atmospheric pressure = 972 B.t.u.

r_1 = latent heat of steam entering calorimeter at initial pressure.

q_2 = heat in the liquid at initial pressure, 180 B.t.u.

q_1 = heat in the liquid at initial pressure.

ts = temperature indicated by thermometer No. 2.

t_2 = temperature of saturated steam at atmospheric pressure = 212 deg.

Testing a Sample

Example—In testing a sample of steam, thermometer No. 1 indicates a temperature of 358 deg., and No. 2 a temperature of 262 deg.—what is the quality of the steam?

Referring to a steam table, we find that a temperature of 358 deg. corresponds to a gage pressure of 135 lbs.; also we find for this pressure, that r_1 =

(Turn to page 46)

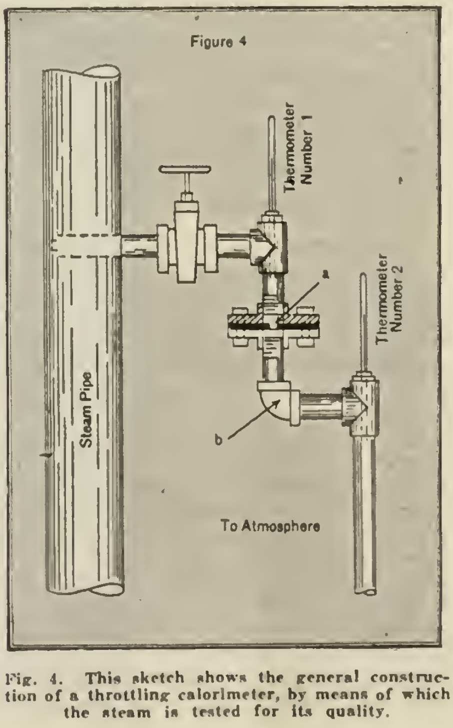


Fig. 4. This sketch shows the general construction of a throttling calorimeter, by means of which the steam is tested for its quality.

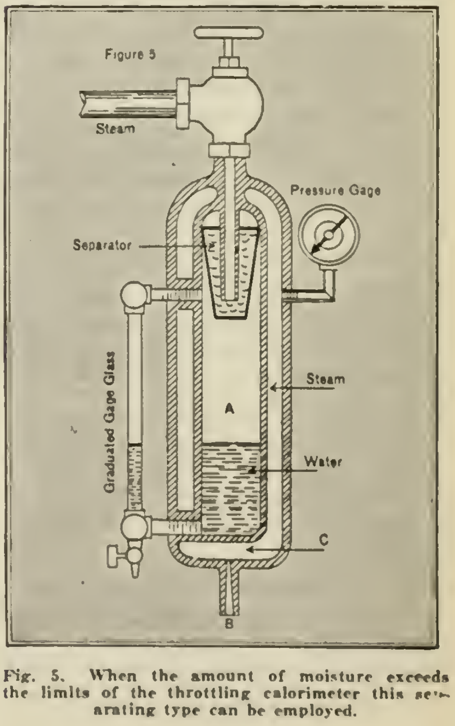

Fig. 5. When the amount of moisture exceeds the limits of the throttling calorimeter this separating type can be employed.

How to Repair Electrical Indicating Instruments

***By VICTOR H. TODD**

Power Plant Engineers Should Always Have the Moving Element in Good Mechanical Balance—The Pointer Should Indicate Zero No Matter in What Position the Instrument is Turned

TWO conditions exist when an indicating instrument is not in order. The instrument may not indicate at all, that is, it not only does not indicate properly, but the pointer does not move appreciably and there is no indication whatever. Or the instrument may indicate but not indicate properly.

When an electric measuring instrument fails to indicate, the trouble may be caused by one of four defects: (1) lack of current or voltage, (2) open circuit in the instrument, (3) short circuit of measuring element and (4) mechanical difficulties. The first three are purely electrical defects and can be located by the proper use of additional instruments, while the fourth can be located usually by a close inspection.

For mechanical troubles, a kit should be used. This contains necessary tools such as large and small pliers, wrenches, screwdrivers, soldering copper, eye-loop, magnet cleaner, tweezers, soldering flux, etc.

An Important Item

The soldering flux is an important item, as one of the first rules of instrument repairing is that fine wires or springs must never be soldered with any paste or flux containing the least acid. There are several acid-free compositions on the market, but an unexcelled paste is made by dissolving powdered rosin in alcohol and adding a little glycerin to prevent drying or caking. This must be used with thin wire-solder and a well-tinned soldering copper to produce perfect electrical connections. No acid or salammoniac and zinc chloride should be used.

Let us assume that a direct current voltmeter suddenly ceases to indicate. The first point is to see if it is caused by line trouble.

Connect a portable standard voltmeter across the terminals of the non-operating voltmeter. Lack of indication denotes line trouble and the voltage should be tested nearer and nearer the bus or generator until the cause can be located. Loose connections or blown fuses often cause a lack of indication. If there is an external resistor in series with the voltmeter, connect the portable instrument across the line sides of the voltmeter and resistor to ascertain that the line voltage is on; then connect the voltmeter across the external resistor.

Indication on both instruments shows an open circuit in the resistor; lack of indication shows open circuit in the voltmeter indication of portable instrument alone shows short circuit or mechanical troubles in the voltmeter.

Lamps May Not Light

If a portable standard voltmeter is not available, then low wattage lamps (5 or 10 watts) may be used to advantage, except that in some cases the lamps may not light because of high resistance in the voltmeter.

If the voltmeter shows open or short, this may further be confirmed by disconnecting one terminal and connecting the standard in series where lack of indication shows open circuit in either voltmeter or resistor and indication shows either "short" or mechanical troubles in the voltmeter.

"Opens" in the potential circuits of wattmeters, watthour meters, frequency meters, power factor meters, reactive factor meters, and synchronoscopes can be detected as shown above, provided the other circuits of the instruments are functioning correctly. "Shorts" may be determined in the above instruments except those where the total impedance of the potential circuit is in the measuring element, as in the watthour meter. In this case, however, a mild short circuit does not cause non-registration but causes increased registration, while a large short circuit eventually causes a burn-out and open-circuit.

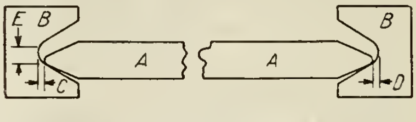

Fig. 1. Diagram of shaft showing end play and side play.

Millivolt meters are tested exactly like voltmeters, except that a portable millivoltmeter should be used in the test. Self-contained ammeters should be tested with a similar range portable instrument, by connecting in parallel, to indicate the presence of current. If the ammeter is open in the main winding, this results in the completion of the circuit and main line current on the portable. Half line current on the portable indicates either electrical or mechanical trouble in the measuring element.

Wipe Off Dust

Let us assume that our original voltmeter has been proven intact electrically but still does not indicate. First, wipe all dust or dirt off the cover and then remove it carefully. Give the pointer a gentle push with a matchstick or toothpick to see if it is stuck (meter elements are usually alive and should be touched with caution). Possibly, it will stay wherever it is pushed and will not return freely to zero. Now disconnect the voltmeter and remove from the board.

One of the most important mechanical points in an electrical instrument is the correct adjustment of "end play." This is illustrated in Fig. 1 where enlarged and exaggerated views are shown of the shaft A with glass-hard pointed ends and sapphire jewels B and B. The total distance C plus D that the shaft can move from end to end is called the "end-play" and the distance E that the pivot can move from one side of the jewels to the other is called the "side-play."

End-play and side-play are usually only a few thousandths of an inch and upon the correctness of this detail depends much of the success of the instrument. A most important rule of instrument repairing is, never screw the jewel-screws in until they clamp or pinch the moving element; even once may ruin the pivots.

Side-Play Adjustment

Correctly designed jewels and pivots, usually, require adjustment of only "side-play" which is done as follows: Lay the instrument on its back and grasping the pointer gently but firmly with either tweezers or thumb and finger, wiggle it gently back and forth, meanwhile tightening the jewel screw with a screw-driver a fraction of a turn at a time until it wiggles only a few thousandths of an inch (about the width of a paper) and then holding the driver firmly, but not pressing down, tighten the jewel lock nut with a suitable wrench.

It may be superfluous to caution the repairman to ascertain that the pivots are actually in the polished recess in the jewel in making this adjustment and not in a crack between jewel and mount, but many pivots are ruined from this oversight.

The deflection of the induction type instrument varies slightly with frequency changes. This is not objectionable when the instruments are used on an ordinary power system. The small variations of frequency have no influence upon their reading. The latest designed instruments are of the dynamometer type; they read practically the same up to 133 cycles.

The best induction type instruments are the least affected by stray fields and static charges. The well designed iron case of dynamometer type meters will shield well the stray field encountered in general switchboard practice. The protective influence of the shield falls off as its mag-

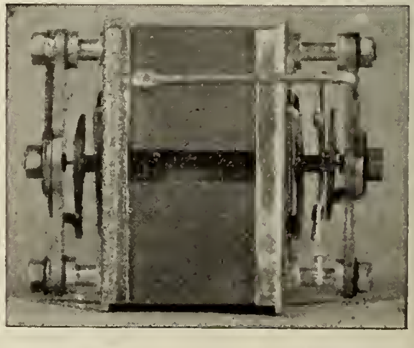

Fig. 2. End view of pole piece core assembly with springs and moving elements showing bearings and parts.

---

*Engineer, Westinghouse Electric & Mfg. Co.

netic density increases and disappears entirely at saturation.

Effect Is Noticeable

With the induction type instrument, the effect is only noticeable when the stray field is exactly in synchronism with the current in the instrument. In such cases the distance between the instrument and the current-carrying bus should be

$$\frac{\text{current}}{5} \text{ inches}$$

Instruments are also susceptible to external electrostatic effects. These effects usually manifest themselves by an attraction of the pointer toward the glass or case. Under certain conditions, by clearing and rubbing the glass in the cover with a soft rag, the pointer of such an instrument may be moved a considerable distance up scale and remain there for some time.

Direct current instruments using permanent magnets, under normal conditions, have small errors due to external field, but may be permanently affected by such fields under short circuit conditions. The minimum distance between an instrument and a current carrying wire or bus bar should be

$$\frac{\text{current}}{5} \text{ inches}$$

in order to protect the instrument.

Temperature errors in instruments are due to changes in physical dimensions and changes in electrical constants. It will be remembered that there are two active forces in an instrument; the deflecting and the restraining forces. The deflecting force is the product of the actuating current, and the strength of the reacting element.

If the temperature of an instrument increases, it may increase the resistance of its windings; this in turn lessens the current and results in a lower deflection. This is further aggravated by the weakening of the magnetic system due to heating. On the other hand, increased heat tends to weaken the restraining control spring, which tends to produce a higher reading. The correct balancing of these two opposite effects is one of the great problems of design and has been so nearly perfected that the actual error in the best instruments is well within the limits of commercial accuracy.

Mechanical Changes

Mechanical changes are also possible due to heating; for instance, heating may distort a coil, or expand a shaft and smash the pivot ends. The first is overcome by a thorough seasoning of all parts, and the second by correctly designing the shaft so that it has the same coefficient of linear expansion as its supports.

Heating errors are produced from two sources: ambient temperature and self-heating. Over the first, the manufacturer has no control, other than to recommend that the instruments should not be used in places subjected to excessive temperatures, if at all avoidable. The second point is taken care of by means of external shunts and resistors, thus liberating the heat where it will cause no errors, instead of in the instrument cases.

An amount of energy insufficient to cause heating alone will operate the moving elements of any fairly good instrument. It is, generally, the excess energy consumed in series resistors and shunts which causes the excess temperature. The errors due to mechanical causes are, probably, of greater importance than purely electrical errors, as the causes leading to them, reduce also the life of the instrument and increase the errors with use and time.

Other things being equal, the frictional error of an instrument is proportional to the ratio of torque to weight of the moving element.

Absolute Cleanliness

Success in instrument work comes only with absolute cleanliness, as the greatest enemy of an instrument is iron filings and dirt; sooner or later they find their way into the air gap and stop the moving element. To inspect the air gap of a direct current instrument, push a piece of white paper between base and element and then holding the instrument so that the light shines on the paper, look through the air gap as shown in Fig. 3.

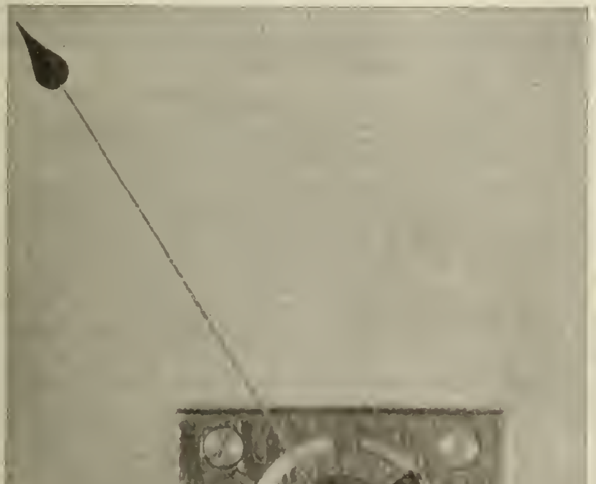

Fig. 3.—Instrument in position for inspection of air gap.

A magnifying glass may be used to advantage, and the least filing or hair or fuzz or dirt should be carefully removed. Iron filings can best be removed by using an iron wire or unbent paper clip, and dirt and fuzz removed by using the tweezers or an ordinary chicken-wing feather. Other defects such as loose wire or parts out of alignment are easily discernible by a simple inspection and are, generally, repairable.

A good instrument should always have the moving element in good mechanical balance; i.e., the pointer should indicate zero no matter in what position the instrument is turned. To secure this, the best instruments have threaded weights, although the principle of balancing is the same in all cases.

Lay Instrument Flat

The first step is to lay the instrument flat on its back and set the pointer on zero. Then hold the instrument so that the pointer is horizontal and adjust the weight on opposite end of pointer so that it again indicates zero; then turning the instrument so the pointer is vertical, adjust either weight until it again indicates zero. Recheck and adjust the other positions if necessary. The instrument should now be in perfect mechanical balance.

After final inspection, the instrument may be retested and replaced on the switchboard.

After the instrument is repaired, it may be found that it is in serious error due to a variation in spring strength or magnets. Or it may be desired to change the capacity of the instrument by changing the spring strength. In either case, it is necessary to measure the "torque" or deflecting force of the instrument, usually expressed in "milligrams." Turn the instrument so that the full scale mark is in a horizontal line with the pivot and then hang a small weight on the pointer, until it deflects the pointer to full scale. Measure the distance from the center of the jewel to the center of the rider in "millimeter," using a pair of dividers if necessary and multiplying by the weight of the rider in "Grams." Their product is the torque of the instrument in "millimeter grams." In the absence of metric standards, the torque may be calculated in "Inch-Ounces" using a copper wire table to obtain the weight of the wire used and reduce to "millimeter grams" by multiplying "Inch-Ounces" by the constant, 718.8.

Assume for example that a piece of No. 24 B. & S. G. copper wire one inch long balances at a distance of 2.25 inches out. From a wire table we learn that No. 24 copper has a weight of .001223 lbs or .019568 oz. per foot; or 00163 oz. per inch. Multiplying by 2.25 inches gives .003667 inch-ounce torque. Multiplying by 718.8 gives 2.635 millimeter grams torque.

If the scale deflection is 90 degrees, and two springs are used, then the torque of one spring will be 1.317, for 90 degrees or

Easy Engineering Lessons in the Power House

By **M. BARRY WATSON, B.A.Sc., M.E.**
Director of Engineering, Central Technical School, Toronto.

STEAM QUALITY

TO KEEP the efficiency of a steam plant high, the steam must be kept as dry as possible. In order to know the quality of the steam, or the amount of moisture in it, we use special instruments known as steam calorimeters.

The word calorimeter means an instrument for measuring heat. It will be seen from what follows that with some types of calorimeters we do make calculations involving the quantity of heat in order to determine the quality of the steam. The name calorimeter has, however, been used to include all types of quality-of-steam measuring devices even though with some of them the heat of the steam does not enter into the problem at all.

On the other hand a steam calorimeter must not be confused with a fuel calorimeter, which is an instrument for measuring the heat value of a fuel.

In the case of superheated steam we can by means of the pressure gauge and a thermometer determine the amount of superheat in the steam by referring to a steam table. These instruments alone will not, however, give us any indication of the quality of or the amount of priming in saturated steam. This is because the temperature of boiling water, dry saturated steam or any mixture of them is always the same at any particular pressure.

Heat Content Less

From a study of the tables of the properties of saturated steam, we know that the heat content of boiling water, at any temperature at which we commonly use it, is much less than the heat content of dry steam at that pressure and temperature. The difference between these quantities is known as the latent heat of evaporation at that temperature.

Thus, if we know that we have 0.97 pounds of dry steam mixed with, say, 0.03 pounds of moisture, we can, by using the steam tables, calculate the heat of a pound of the mixture, or the heat content of a pound of steam of quality 0.97.

Conversely if we can find some way of measuring the total heat of a pound of steam at a certain pressure we will be able to work out the quality of the steam. This is the principle on which one of the simplest types of calorimeters operates.

The Barrel Calorimeter

While not absolutely accurate, the barrel calorimeter is the simplest and least expensive. It consists of a wooden barrel, about 60-gallon size, mounted on a scale for weighing. A sampling pipe is connected to the steam main or boiler and is connected through a valve and piping to a piece of rubber hose which can readily be inserted into the barrel to about two thirds of its depth.

The method of operation is simple. The barrel is weighed when empty, it is then filled about two thirds full of cold water and weighed again. The difference in the weights is the weight of the cold water. The temperature of the cool water is taken just before the test is to be made, making sure the water is well mixed up.

Steam, the pressure of which in the main is read both on opening and closing the valve, is then admitted through the hose pipe, which is held under water, and the steam is condensed by the water until the temperature of the water is raised, say, 60 to 100 degrees. The steam is then shut off, the hose pipe removed but allowed to drain into the barrel, and the temperature of the water is read, making sure it is thoroughly mixed up so that the temperature is the same in all parts of the water.

This reading of temperature should be taken as soon as possible, because heat is being lost through the air and the sides of the barrel all the time. Then the final weight of the barrel of water is found.

A Typical Case

Example:—Suppose the following readings were obtained:

Weight of barrel, empty, 180 lbs.

Weight of barrel and cold water, 635 lbs.

Weight of barrel and hot water, 675 lbs.

Temperature of cold water, 50 degrees Fahr.

Temperature of hot water, 140 degrees Fahr.

Average steam pressure, 60 pounds per square inch gauge, or about 75 pounds per square inch absolute.

Since we know that the specific heat of water is 1, or that it requires one B.t.u., to raise the temperature of one pound of water through one degree Fahr., also that the heat content of water or steam is measured from that of water at 32 degrees F.; we find that each pound of water at 50 degrees contains 50 — 32 = 18 B.t.u.'s. Also at 140 degrees, each pound of water has a heat content of 140 — 32 = 108 B.t.u.'s. We have then:

Total weight of cold water = 635 — 180 =455 lbs.

Total weight of hot water = 675 — 180 = 495 lbs.

Total weight of wet steam = 495 — 455 = 40 lbs.

The cold water has been raised in temperature 140 — 50 = 90 degrees, or has had added to it 455 × 90 = 40,950 B.t.u.'s. This heat must have come from and will therefore equal that given up by the steam in condensing and cooling down to 140 degrees.

Consult Steam Tables

By consulting the steam tables we find that for a pressure of 75 pounds per square inch absolute, the total heat content of one pound of dry steam was 1,181.1 B.t.u.'s, while that of water at the same temperature is found to be 277.4 B.t.u.'s.

Let X be the proportion of dry steam in the steam supplied to the barrel. This should be expressed as a decimal of the whole. Then the total amount of dry steam that was condensed was 40 × X lbs., and the amount of water in this steam was 40 × (1 — X). When it is condensed the dry steam gives up its latent heat, which is 1,181.1 — 277.4 = 903.7 B.t.u.'s per pound.

The total amount of latent heat given up by this steam will be 40 × X × 903.7 = 36,148 X. Besides this latent heat there is given up heat by the condensed steam and the moisture along with it, in cooling from 277.4 degrees to 108 degrees. For the whole 40 pounds this will amount to $40 \times (277.4 - 108) = 40 \times 169.4 = 6{,}776$ B.t.u.'s. Thus the total heat given up by the steam in condensing the dry part and cooling all down to 108 degrees was $6{,}776 + 36{,}148$ X B.t.u.'s, which we said above was equal to the heat added to the cool water or 40,950 B.t.u.'s; thus we have an equation

$$40{,}950 = 6{,}776 + 36{,}149\,X$$

or $$36{,}148\,X = 40{,}950 - 6{,}776 = 34{,}174$$

therefore $$X = \frac{34{,}174}{36{,}148} = 0.945,$$ which is the quality of the steam.

This may also be expressed as 94½ per cent. dry, or 5½ per cent. wet.

The barrel calorimeter is naturally inaccurate, because no account is taken of the amount of heat that is absorbed by the barrel itself, or that given off to the atmosphere. However, results obtained by its use are sufficiently accurate for all but exact calculations, and it is, of course, a splendid check on the constancy of steam quality.

The Separating Calorimeter

The second type of calorimeter from the point of view of simplicity is known as the separating calorimeter, and is, in effect, a steam separator. The separating calorimeter belies its name in that it has nothing whatever to do with the heat value of the steam, except that once knowing the quality of steam its heat value may be calculated from the steam tables.

The operation of the separating calorimeter is identical with that of a steam separator. In its passage through the separator the steam is forced to make one or more sharp turns, the drops of moisture having greater density than the steam tend to travel on in straight lines and are collected in a reservoir, while the steam passes out of the separator with practically no moisture in it.

In the simple type of separating calorimeter the water collected must be drawn off to be measured, and the dry steam must be condensed in order to be weighed. In this way we can find directly the proportion of the moisture to the mixture, which, when expressed as a decimal or a percentage is the quality of the steam.

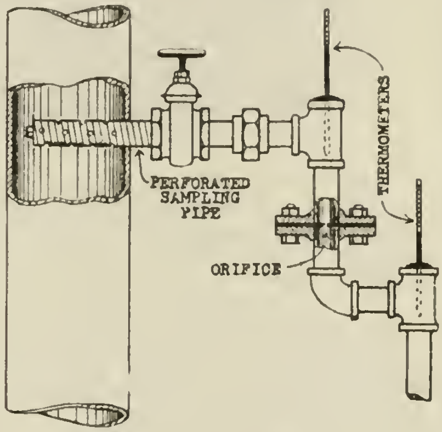
In the more elaborate types there is a gauge glass on the reservoir with a scale to show pounds of water collected, and the orifice through which the steam escapes is so calibrated that for each different steam pressure there is a corresponding definite amount of steam discharged per minute. There is also mounted on the calorimeter a pressure gauge with an extra scale graduated to show the flow in pounds of dry steam per minute.

Must Be Warmed Up

In using the separating calorimeter the instrument is connected by a short nipple and valve to the sampling pipe in the steam main, and is thoroughly lagged with hair felt. It must be warmed up by passing steam through it before commencing the test. The test should be made with a flying start. In the simple type the height of the water in the gauge glass should be marked and the weight of the condensing tank taken at the same instant; after several minutes the same readings are taken again.

The difference between the weights of the condensing tank show directly the amount of dry steam passed during the time chosen. The calorimeter reservoir, after turning off the steam, should be drained down to the second mark. Then it should be drained down to the first mark into a weighed vessel. The weight of this water between the two marks is the amount of moisture in the steam.

In using the calibrated type it is merely necessary to read the water gauge at the beginning and end of, say, 10 minutes. One tenth of the water collection will then be the amount of priming in the steam passed in one minute. The pressure gauge is read on the pounds-per-minute scale every minute or half minute and the average of all the readings is the amount of dry steam per minute.



The Steam Calorimeter

Weight of Dry Steam

Let W represent the weight of dry steam passed per minute or during the whole test as the case may be, and w represent the weight of priming collected in the same time. Then the total weight of wet steam used will be W + w, and the proportion of priming or moisture will be $\frac{w}{W + w}$ while the quality of the steam will be $\frac{W}{W + w}$ or expressed as a percentage will be $\frac{100\,W}{W + w}$ per cent.

Example:—Suppose the weight of dry steam collected or passed per unit of time was 72 lbs., and the amount of moisture separated 4.8 lbs., the quality of the steam will be

$$\frac{72}{72 + 4.8} = \frac{72}{76.8} = .938.$$

and the percentage of moisture

$$\frac{4.8}{72 + 4.8} = \frac{4.8}{76.8} = .062.$$

The separating calorimeter is more accurate with poor quality steam, or a high proportion of moisture, because it does not separate quite all the moisture from the steam. However, for steam having five per cent. or more of priming, it is fairly accurate.

The Throttling Calorimeter

The third type of calorimeter, which is very simple in its construction, though somewhat involved in the computation of results, is known as the throttling calorimeter. A simple home-made form of this calorimeter is shown in the illustration. In use it should be lagged to prevent the radiation of heat. It consists of a thermometer cup on the supply pipe, a small orifice through which the steam is throttled and its pressure reduced, and a second thermometer cup in the low pressure side.

The inlet is connected to a sampling pipe with short connections, as shown, and the exhaust is allowed to escape to the atmosphere or to any other low pressure. If the exhaust goes other than direct to the atmosphere, a pressure gauge is also needed on the low pressure side.

The action of the throttling calorimeter is as follows: When the wet steam passes through the small orifice its pressure drops; and since low pressure dry steam contains much less heat than high pressure steam, there will be more heat in the original dry part of the steam than is required to keep it dry at lower pressure, and this heat is used to evaporate any moisture that may be present; if there is no moisture to be evaporated the excess heat superheats the steam. Since the high pressure steam is wet, saturated steam, we know by reference to a steam table its temperature and its pressure, if we know either of these quantities.

To know the condition of the superheated steam in the body of the calorimeter we must know both its temperature and its pressure. Therefore, the readings which we are required to make in using this type of calorimeter are temperature or pressure of the high pressure steam and temperature and pressure on the low pressure side of the orifice.

It is generally easier to read a thermometer accurately than to take accurate readings on a pressure gauge, therefore temperature, instead of pressure, is usually read on the high pressure side of a throttling calorimeter. In case the discharge takes place from the calorimeter, at atmospheric pressure, we will either assume that the temperature of saturated steam is 212 deg., and subtract that from the temperature shown on the low pressure thermometer to find the amount of superheat, or in very accurate work we may read atmospheric pressure from a barometer and the gauge pressure in the calorimeter by means of a monometer, a draft gauge reversed, and find the true corresponding boiling point from the steam tables.

Electricity in the Power House

By J. A. BURNETT, M.E.I.C., Consulting Engineer, 205 St. James St., Montreal

SOLDERING JOINTS

CLEAN and hot, are two essentials of a good soldered joint, which must be kept in mind on every job.

In making an ordinary spliced joint, the wires are bared of insulation for a distance of about one inch from the joint and carefully cleaned by the use of sand paper or emery cloth. Emery cloth is preferable because it is tough and flexible and a rapid scouring of the surface can be made.

The two ends of the cleaned wire are butted together after slipping over them a carefully prepared sleeve. The surfaces may be brushed with a solution of sal-ammoniac, or preferably, coated with a soldering paste.

A solution of resin in alcohol is sometimes employed for this purpose. The joint is now ready for the application of the solder.

Flows Readily

It is heated by a hot soldering iron or in the flame of a gasoline torch until the application of a soldering stick to its surface shows that the solder will readily flow over the cleaned surfaces.

Certain precautions must be observed in heating the joint, as, for instance, not to get the surface too hot, as the copper will then oxidize. Neither must the surface be too cold, as the solder will not then readily flow, as a consequence of which the joint may be imperfectly united, or because of frozen dripping, it will present stalactitic points which have to be cut or filed off before taping the joint.

It is absolutely necessary that the soldered joint have a smooth surface, otherwise the insulation will be cut.

If, however, the joint need not have mechanical strength and is only required to be electrically conducting, the use of a sleeve may be dispensed with. The wires may then be placed side by side and overlapped, wrapped with fine copper wire, about No. 26 in. size. The fine wire holds the joint in position.

Care should be used in wrapping, that the untaped wire presents no sharp points. Solder is now flowed on as before. After a sufficient amount has been put on to cover the surface and the interstices of the fine wire are filled, it is advisable to wipe the joint with a cloth just as a plumber does in wiping a joint.

This removes any excess of solder and makes the joint smooth on its surface.

If the conductor is two wires in multiple and it is desired to solder it to a similar pair of wires, it is usual to cut one wire of each pair half an inch to an inch shorter than the other and then place the two conductors together.

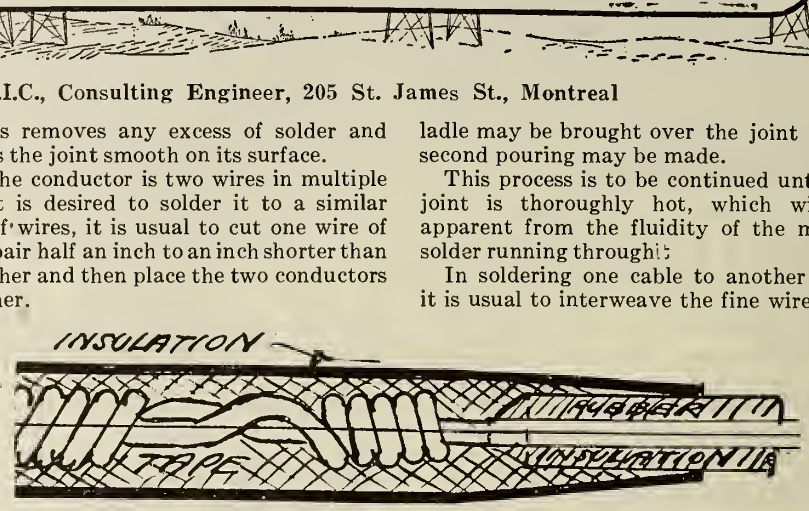

Fig. 2

These may be wrapped as above and their soldering then presents no difficulty.

Obviously, this may be extended to the soldering of any number of conductors in parallel.

Solder Copper Strip

It is sometimes necessary to solder a sheet copper strip to a wire in order to provide a flexible lead for wires of large size. After the surfaces are cleaned, one end of the copper strip is formed to fit the wire to which it is soldered.

After fluxing, the soldering operation is performed as usual.

If a single copper strip does not provide sufficient conductivity for a wire cable, two or more of them are placed in parallel upon it, in which case difficulty is apt to be experienced from the flowing of solder between the strips.

Solder will always run on hot copper. To obviate this difficulty it is usual to place strips of material between the sheets of copper to prevent their being united by the flowing solder.

Copper wire up to the size of No. 0 may readily be soldered by a soldering iron of the usual size, say an inch and a quarter square.

With larger sizes a gasolene torch must be used unless one has a pot of hot solder with two ladles, when the hot solder may be poured upon the ladle directly on the joint. This can be accomplished by pouring upon the joint and catching the drip in the ladle underneath the joint.

If the joint is such a size that it is not warmed at the first pouring, the lower ladle may be brought over the joint and a second pouring may be made.

This process is to be continued until the joint is thoroughly hot, which will be apparent from the fluidity of the molten solder running through it.

In soldering one cable to another cable it is usual to interweave the fine wires to a sufficient length and then wrap the whole with fine wire, after which it may be treated in the usual way.

When a cable is to be inserted in a sleeve or terminal plug it may be dipped in the soldering fluid and then plunged into molten solder.

The plug in which the cable may be placed can be tinned in the same manner. The receptacle of the plug is now filled about half full of solder, when the tinned cable may be plunged into it.

The sleeves used for soldering joints are made of copper or brass tubes, slotted end to end to permit solder to run in, and tinned.

Fig. 1 shows one type of sleeve.

The joints are often insulated by means of friction tape, but it is advisable to use a coating of rubber tape first, then to apply friction tape. The joint is then well painted with insulating paint.

Fig. 2 shows this feature and the "scarfed" insulation, on a joint.

One of the writer's early jobs was the erection of a low voltage generator where large cables had to be run from the machine to the switchboard.

Cast brass terminals were to be soldered on the ends of these cables. Local workmen who had applied to the writer for work were given the task.

They were fairly good mechanics along certain lines, but they were not accustomed to soldering.

When the writer returned to the work after a short absence, suspicions were aroused by the rapidity with which it was progressing, so one of the soldered terminals was given a few raps with a hammer, whereupon it promptly fell off.

The solder and terminal had been heated all right, but the cable had not been heated sufficiently to keep it from "freezing" the solder when inserted into the terminal, and the torch had not been applied to the terminal long enough to sweat the solder into the cable.

The inside of the terminal had not been properly cleaned and tinned, so the solder did not adhere.

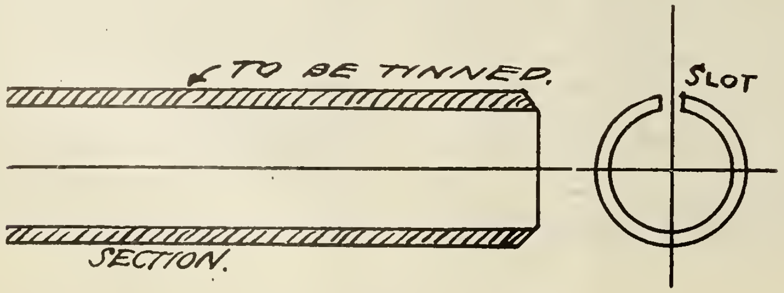

Fig. 1

Practical Ideas From Practical Men

LATCH-HOOK SPRING

The spring on the latch-hook of a Corliss engine valve gear gave us no end of trouble some time ago. The spring as originally supplied with the engine was made of a thin flat spring and fitted as shown in Fig. 1.

Trouble was experienced with the springs after they had been in service a short time, breaking off at A Fig.1. Some of the springs would last only a day and as the supply of springs soon ran out and were difficult to get, it was decided to use a different type which could be readily procured.

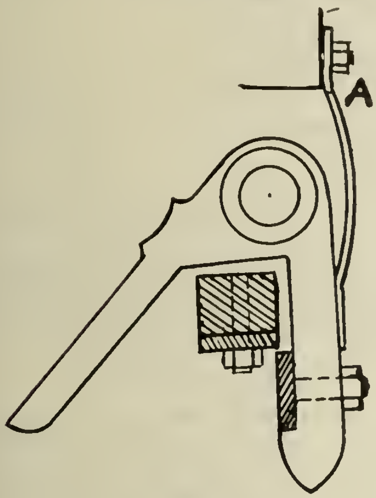

Fig. 1.

The new arrangement of the spring is shown in Fig. 2. A strip of steel one inch wide and one-eighth inch thick was bent as shown at F. A block of brass B with a small hole in it to act as a guide for the bolt through the spring was soldered to the valve gear.

Instead of a flat steel spring, a helical spring H was used as shown in the drawing.

With the new spring system on the engine all troubles from that source were ended. The whole job was rushed in order to have the engine idle as short a time as possible, so it was not made as carefully as it would have been had more time been available, but so well has the temporary affair worked that nothing has been done in the way of repairs for several years.—T. H. HOPE, Toronto.

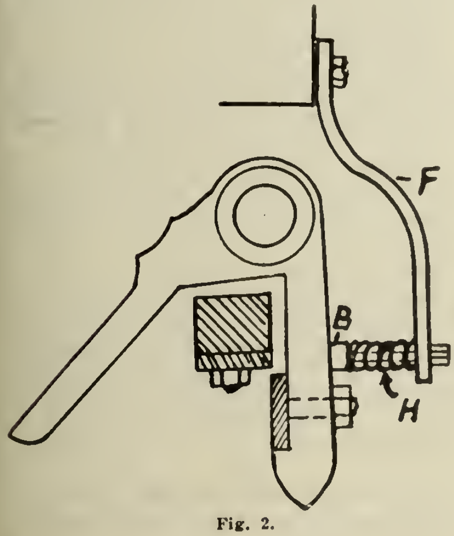

Fig. 2.

EYE PROTECTION

We read and see much about safety first, and still more about economy, yet there is a common, every-day occurrence in our boiler rooms that is contrary to both precepts. We all seem to accept it as an unavoidable evil, although its elimination pays splendid dividends.

The evil is the intense brightness and heat to which the fireman exposes his eyes every time the door of a hand-fired furnace is opened.

This evil is a costly one on coal consumption and should be stopped for that reason, as well as for the comfort of the fireman. As eyes are one of the most essential organs of firemen, whether off or on duty, they should receive protection from the bright light and heat, as much as possible. If not, strained eyes, stomach trouble, lack of ambition, and a general run-down condition will result.

This may seem "tommy rot" to some engineers, but to me it is a reality which has cost me real money. When I was striving to find something to protect my eyes, I found that with several of the devices on the market, I could see through the flame to the coal bed, which was uneven with some holes through to the grates. These holes were near the bridge wall, and hidden from the view of the naked eye by the flame in the front portion of the furnace. I levelled out my fire and my coal, where needed, and in this way was able to come up on the CO_2 from 11 to 13 per cent., holding it there as easily as I could at 11 per cent. without the eye protector.

Tries Smoked Glasses

The usual devices to protect the eyes are similar to those used by oxygen welders, but as I was exposed to conditions which made these neither comfortable nor serviceable, I used smoked glasses, later trying a green celluloid shade with excellent success. In selecting a shade the engineer will find there are several different kinds on the market, but the one best suited to the fireman's purpose is the kind through which you can clearly see the wires of an electric bulb.

Personally, I think that a good eye shade used as above described is as good a fuel saver as either a draught gauge or a the:mometer.—C. RYE, Wesley College, Winnipeg.

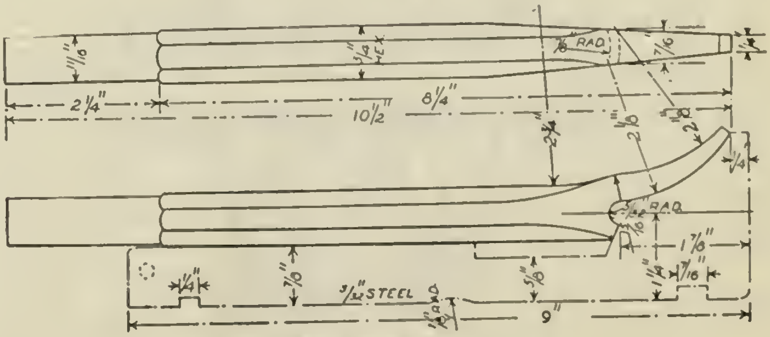
FLUE BEADING TOOL

The accompanying illustration shows with full detail measurements of the standard flue beading tool that has been found to be very efficient and satisfactory on locomotive boilers.

It is 10½ in. long over all and is made of hexagon steel. The forming curve is of 5/32 in. radius so as to form a 5/16 in. bead at the end of the tube and the heel and toe are cut at such an angle and given the proper curve to facilitate the upsetting and belling of the end of the tube so as to put it in shape for the final beading.

In connection with the beading tool a template for making it is also provided. This is shown by dotted lines as lying against one side of the lower drawing of the tool. It has a bevel that bears against the heel with a projection fitting into the beading groove and then fits against the curve up to the tip that serves as a fulcrum for the belling out of the tube.

On the lower face of the template there are three grooves: one ¼ in. wide, one 7/16 in. wide and one cut to a radius of ⅞ in. These serve respectively for bringing the tip and heel to proper widths and the heel to a proper radius. It is thus possible to make all of these tools alike and with the minimum of trouble. —A. SMYTH.



Flue Beading Tool.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

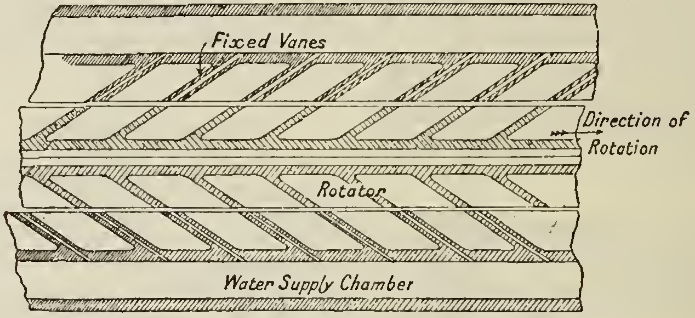


Fig. 2—Section Showing Vanes.

WATER DYNAMOMETER

How is the ordinary water dynamometer constructed and how is it used to measure the horsepower of an engine?

—H. H. CURTIS, Edmonton.

Ans: The ordinary water dynamometer or, as it is sometimes called, the "Froude," is shown in section in Fig. 1.

It consists of two main elements, a case or shell in which revolves the wheel or the rotor, the latter being a circular disc. On each side is formed a circular channel of semi-elliptical cross-section. These channels are placed back to back and are provided with a number of vanes fixed obliquely, as shown in section in Fig. 2.

On each side of the casing, similar channels are fixed, also provided with vanes, thus forming two complete annular channels of elliptical cross-section, the channels being divided into a number of complete compartments by the oblique vanes.

When the rotor is set in motion and the whole internal space filled with water, the water in the cups of the rotor, due to centrifugal force, passes to the outer surface and is thrown with considerable force against the upper part of the fixed cups in the casing.

The water then circulates around the outer surface of the fixed cups and enters the bottom edge of the cups with increased velocity. A whirlpool is thus set up in each cup, the power required to keep the rotor going being mainly used up by these eddies.

The whole of the power used being turned into heat, as in the case of the ordinary Prony brake, a continual supply of cold water is necessary to keep the machine cool.

In using the machine, the rotor is lined up with the engine or motor shaft and connected to it, and the supply of water to the machine regulated according to the load.

The friction of the water tends to cause the casing to rotate with the impeller or the rotor, this tendency being resisted by a lever fastened to the casing and bearing on the platform of a scale.

The horsepower is calculated the same as for the Prony brake:

$$\text{H.P.} = \frac{2\pi LN(W—W_1)}{33{,}000}$$

where

L = length of the brake arm in feet.
N = revolutions per minute.
W = Total weight on scale.
W_1 = Tare weight on scale.
W—W_1 is thus the net weight on the scale.

The friction of the shaft bearings acts in the same direction as the water in the rotor, thus introducing no error in the readings.

Water should be supplied under pressures from 10 to 30 lb., and for water at 70 deg. F., about 3 gallons per brake horsepower hour are required.

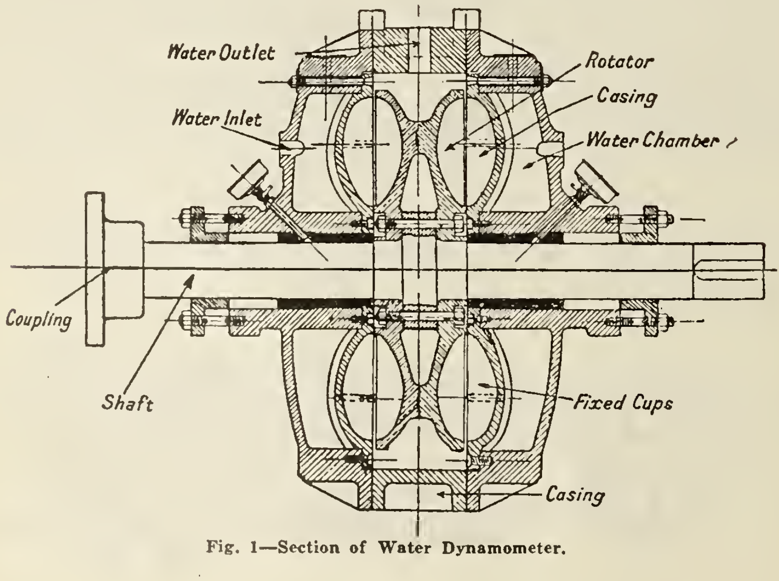

Fig. 1—Section of Water Dynamometer.

* * * *

LOSSES IN ELBOWS

A boiler rated at 30 h.p. is connected to a 10 x 10 steam engine running at normal speed of 310 r.p.m. Steam is conveyed to the engine through a 2½ in. pipe, 16 ft. long. The pipe line contains 6 90-deg. elbows. The steam pressure carried is about 90 lbs. gauge. Would the engine give any more power if the pipe line contained no elbows?

—CORNELIUS MURPHY,
Melrose, N. B.

Answer:—From the information you have given, it is not possible to work out with any degree of accuracy the gain in power if all the elbows were eliminated from the pipe line, from the boiler to the engine.

You do not give the load on the engine nor do you say whether the steam pipe is covered with a good heat insulating material or whether it is exposed.

In the first place, a 10 x 10 engine is capable of using much more steam than a 30 h.p. boiler can produce, especially if the engine is in bad shape and the boiler is dirty or scaled up badly.

Suppose the engine is using the full 30 h.p. from the boiler. One boiler h.p. is equivalent to 34.5 lbs. of water evaporated from and at 212 deg F.

Using a steam pressure of 90 lbs. gauge, the boiler would be using 30 × 29 or 870 lbs. of water per hour. At 90 gauge 4.23 cu. ft. of steam weighs one pound. The volume of the steam per minute flowing through the pipe is

$$\text{then about } \frac{870 \times 4.23}{60} = 61.3 \text{ cu. ft.}$$

The area of a 2½ in. pipe is about 1-30 of a sq. ft., so the velocity of the steam through the pipe must be about 61.3 × 30 = 1,840 ft. per min. This is rather low and at such velocity the loss due to elbows would be small.

It would be advisable, if you have a spare pressure gauge, to place it in the pipe line next the engine, then you could find directly the loss in pressure. A point to be remembered is that all pressure gauges do not read the same. It would be well to check the two gauges before using them, as the drop in pressure will only be a few pounds at best.

Even if there is a considerable drop in pressure in the pipe line, it does not follow that there will be much reduction in power. The drop in pressure has a tendency to superheat the steam and if the pipe is properly covered to retain the superheat due to drop in pressure, better expansion will be secured than with the wet steam, in this way giving back most of the power which is apparently lost due to the reduction in pressure.

The real cause of your trouble is that the boiler is not capable of keeping the engine supplied with steam.

For cut-off at ⅝ stroke, with the ordinary D slide valve engine and steam pressure 90 lbs. gauge, the mean effective pressure is about 63 lbs. per sq. in.

Assume that we have a m.e.p. of 60 lbs. per sq. in. and using the formula,

$$\text{H.P.} = \frac{PLAN}{33{,}000}$$

where P = M.E.P.
A = Area of piston.
L = Length of stroke.
N = R.P.M.

In this case, with the 10 x 10 engine the h.p. developed would be,

$$144 \times 60 \times \frac{10}{12} \times \frac{.7854}{33{,}000} \times \frac{100}{144} \times 310 = 37$$

* * * *

VALVE OPENING

What is the minimum lift required in the ordinary globe valve to give the full opening? In a globe valve, when the lift of the valve is ¼ of the diameter of the opening, is the valve wide open?

—A. L., H. Vancouver.

Answer:—Assume that the diameter of the opening in the valve is one inch.

The area of a circle is .7854 × D^2.

The area of the one inch circle is then .7854 sq. in.

The circumference of a circle is 3.1416 × D.

Now, if the lift of the valve is ¼ in., the area of the opening is then,

¼ × 3.1416 × 1 = .7854 sq. in.

This is the same as the area of the circular hole in the valve, thus, when the lift of the valve disc is ¼ of the diameter of the hole in the valve, it is wide open.

The minimum lift required for the valve to be wide open is clearly shown.

HEATING SURFACE

What is the number of square feet of heating surface in a horizontal return-tubular boiler 72 in. in diameter and 14 ft. long, containing 127 three-inch tubes? —WALTER HUDSON.

Ans: Allowing as heating surfaces, two-thirds of the shell, the internal area of the fire tubes and two-thirds of the area of the heads after deducting tube holes and taking all dimensions in inches, there would be:

In the shell:

Heating Surface sq. in.

Circumference = 72″ × 3.1416 = 226.195″.
2/3 of circumference = 2/3 of 226.195 = 150.796″.
Length 14 ft. × 12 = 168″.
Heating surface in shell = 150.796 × 168″ = 25,333

In the tubes:

Internal dia. of 3″ tube = 2.782″.
Internal circum. = 2,782 × 3,1416 = 8,740.
For 127 tubes 168″ long, 8.74 × 127 × 168 = 186,476

In the heads:

Gross area of two-thirds of two heads = 72 × 72 × 0.7854 × 2 × 2/3 = 5,428 sq. in.
Twice combined area of 127 three-inch tube holes = 2 × 127 × (3 × 3 × 0.7854 = 1,795 sq. in.
5,428 − 1,795 = ...3,633

Total Heating surface 215,442
or 215,442 ÷ 144 = 1,496.12 sq. ft.

* * * *

GAUGE FLUCTUATIONS

What causes water to rise and fall in the glass gage of a boiler?

—A. HOLMES.

Ans: The water rises and falls because there is an actual wave of water within the boiler, or surging due to the circulation.

When there is generation of steam, the circulation of the water has a tendency to drive it higher at one end than the other end of the boiler, which results in a glass gage indication of higher or lower water than the actual average water level. Activity of boiling has a tendency to increase the steam pressure and lower the water level in its vicinity, and near points where the steam pressure is reduced by discharge of steam from the boiler there is a tendency of higher water level.

When a boiler is in operation, these disturbances always are present to greater or less extent, causing the glass gage to indicate higher or lower water than the true or average level.

* * * *

EXPLOSION TEMPERATURES

What is the highest temperature attained in the cylinder of an internal-combustion engine at explosion?

—O. E. WYLIE.

Ans: The maximum temperature that occurs in an internal-combustion engine at the time of explosion varies with the compression that is carried in the engine and also with the amount of fuel added. In the ordinary gas engine, carrying from 80 to 90 lbs. compression, the maximum temperature will be in the neighborhood of 2,700 deg. F.

On the other hand, with oil engines where the compression pressure is carried much higher, the maximum temperature often is as high as 3,500 to 3,600 deg. F. Theoretically, the temperature should reach about 4,500 deg. F., figuring the amount that is normally added to the air charge.

However, there is a very rapid radiation of heat during the period of combustion, and this serves to keep the temperature much below the theoretical value.

* * * *

MOTOR SPEED

Can a 220-volt 5-h.p. 60-cycle induction motor be operated at 1,500 or 2,500 r.p.m? —C.A.S.E.

Ans: A 220-volt 5-h.p. 60-cycle induction motor cannot be changed to operate at 2,500 r.p.m. The speed of an induction motor is fixed by the frequency of the circuit and the number of poles in the motor.

The speed of the motor is equal to 120 times the frequency (cycles per second) divided by the number of poles. On 60 cycles, a two-pole motor will run at 120 × 60 ÷ 2 = 3,600 r.p.m.

A four-pole motor would operate at half this speed, or 1,800 revolutions per minute, and a six-pole motor at one-third this speed or 1,200 r.p.m. From this it will be seen that the three highest speeds that the motor can operate at are 1,200, 1,800 and 3,600 r.p.m.

Of course these are theoretical values, and the actual speed will be about 5 per cent. less than the theoretical.

* * * *

WATER COOLING

How many gallons of water can be cooled per hour from 75 deg. F. to 55 deg. F. per ton of refrigerating capacity? —W. M. T.

Ans: The unit of capacity of a refrigerating machine is taken as the abstraction of an amount of heat equal to the heat of fusion of 1 ton (2,000 lb.) of ice per day (24 hours).

The average heat of fusion is about 143.33 B.t.u. per lb., which is equivalent to 286,660 B.t.u. per ton, or the taking up of heat in a machine of unit capacity at the rate of 199.07 B.t.u. per min. This is so close to the convenient round figures of 200 B.t.u. per min. = 12,000 B.t.u. per hour that these figures are always used for rating refrigerating capacity.

For cooling water from 75 deg. F. to 55 deg. F., each pound of water would require the removal of 75 — 55 = 20 B.t.u., and a ton of refrigerating capacity would cool 12,000 ÷ 20 = 600 lb. of water an hour, and allowing 10 lb. of water per gallon, there would be 600 ÷ 10 = 60 gal. cooled per hour.

Booklet 300 of the Wright-Austin Co., Detroit, describes separators and exhaust heads.

The separators are for oil, gas, or steam, both saturated and superheated, high or low pressures and for vacuum service. Depending on the service, cast-iron, semi-steel, cast steel or boiler plate is used in the construction.

The bulletin also describes exhaust heads, steam traps and low pressure oil traps.

Announcements

James Howden & Co., Glasgow, Scotland, announce the appointment as their sole Canadian representatives of the Combustion Engineering Corporation with offices in Montreal, Toronto, Winnipeg and Vancouver.

Messrs. Howden are well known throughout the engineering world, having been established since 1854. Their manufactures include: The Howden-Zoelly Steam Turbines in all sizes; Vertical High Speed Enclosed Forced Lubrication Engines up to 2,500 B.H.P.; Howden Weir Steam Condensing Plants, and various auxiliaries such as centrifugal circulating pumps and forced draft apparatus, of which latter specialty installations aggregating more than 26,000,000 I.H.P. have been effected to date.

This company have also been the first within the British Empire to adopt and manufacture the Howden-Ljungstrom Air Preheater, which is now said to be one of the most far reaching inventions that has been brought out in years, and is attracting wide-spread attention in all centres.

Messrs. Howden already have a thorough understanding of the Canadian field, having operated in this market for some years, and latterly through their branch works located at Wellsville, N.Y., from which centre they have been enabled to give prompt service. Their most recent large Canadian contract has been an order from the City of Winnipeg for two 5,000 K.W. and one 1,000 K.W. turbo-alternators, complete with condensing equipment which are to be installed in the Municipal Hydro-Electric Steam Standby Station.

The Combustion Engineering Corporation are well known as manufacturers of boiler room specialties, including all types of mechanical stokers, pulverized fuel and oil burning equipment, coal and ash handling apparatus, etc., and the combination in Canada of these two firms for the purpose of meeting both engine room and boiler room requirements is interesting at this time.

The Combustion Engineering Corporation also announce the appointment on the board of directors, with headquarters in Montreal, of F. S. B. Heward, who, for the past five years, has been vice-president and managing director of the Howden Company in America.

The Sanford Riley Stoker Co., Worcester, Mass., have published a new 64-page catalog describing the Riley underfeed stoker.

This stoker is of the multiple retort inclined underfeed type with continuous automatic ash discharge. Beyond the end of the underfeed retorts are the overfeed grates extending across the entire width of the stoker.

Movement of the fuel bed and the dumping of the ash is controlled by the reciprocating sides of the retorts. Ash is crushed at the rear of the stoker by the rocker dump plates. The travel of the reciprocating retort sides is determined by the stroke adjusters.

The stoker is fitted with a two-speed gear box and a renewable cylinder liner, made of a half section of nine inch standard pipe inserted in a counter bored cylinder.

The claims made for the stoker are: smokeless combustion, high capacity with flexibility and high efficiency, ability to burn all classes of fuel, especially coals having a high percentage of ash.

Miscellaneous

Coming back strong after a twelve years' absence from the baseball field Jenkins Bros., stepped right into front place in Montreal amateur baseball.

The Jenkins team playing in the Spalding Intermediate League smashed their way to victory through the regular season at the end of which they found themselves tied with the team of the Grand Trunk Car Shops for first position. The play-off on the grounds of the Imperial Tobacco Co., proved the superiority of the Jenkins men, the final score—after a very keenly contested game—being 11-7 in favor of the valve makers, who thus secured the championship.

QUESTIONS AND ANSWERS

I am engaged and being married next week to a wealthy young engineer—what should I weigh?—Trixie.

Answers:—One can do nothing in a week—after that, why worry?

* * *

If a main journal or crankpin becomes scored, it can be remedied by careful lapping with a canvas strip coated with emery paste. If it persists in running hot, white lead coated over the surface will often smooth it up.

* * *

Old King Cole is a merry old soul,
And I'll tell you why he's that way;
He likes his pipe and he likes his bowl,
And he reads Power House every day.

* * *

In cleaning pistons, a brass scraper should be used; emery cloth is never advisable save in cases of extreme scoring. Pistons should be pulled at least every nine months for cleaning. If the oil is a heavy residuum, more frequent cleaning will be necessary.

* * *

The Windsor fireman was so ignorant—he thought that overhead meant the cost of the roof.

* * *

Many engineers try to weld fractured piston heads. This is seldom, if ever, successful. The only feasible method of repair is that of "sewing" which is successful only in cases where the fracture is not of any great extent. Threaded brass rod makes the best kind of plugs to use in the sewing process.

* * *

Overheard by Walter Hudson on a C.P.R. diner at Winnipeg, between the head chef and another chef who was sent on an errand. Being gone longer than the head chef liked, the latter said to his assistant on his return: "Well, nigger, you can go the fudderest the quickest, and stay the longest, and do the lessest of any nigger I know."

* * *

The specific heat at constant volume in an oil engine is about 0.169. That is, if one pound of air is heated in a confined space (at constant volume) 0.169 B.t.u. are required to raise the temperature one degree Fahr. As the temperature rises, this specific heat changes, but for all practical purposes the value 0.169 may be assumed to be constant for all temperatures.

C. A. S. E. Notes

London No. 30, C.A.S.E., held their regular meeting Oct. 5. President Mott urged every member to do his best to bring No. 30 back to its old standard of membership. Grand Doorkeeper Jos. H. Ward visited St. Thomas last week and expects to have that lodge on the list again with a good working membership.

Having had the honor to be elected door keeper in the executive council C.A.S.E., I take this opportunity of writing a few words to all members in general.

As we are on the eve of a membership campaign and impressive educational lectures, etc., I would say that if each member will put out his best effort I believe we can double our present membership. Why not set the goal for the year at 1,000? I believe it can be done; so let us all do our best and see what we can do to make the next Convention the best ever.—JOSEPH WARD, Secretary Treasurer, London No. 30, Grand Door Keeper.

M.D.E.A. Notes

A regular meeting of the Montreal & District Engineers Association was held on Oct. 26 at the Royal Arcanum Chambers. At the close of the meeting, W. H. Rose, the treasurer, was presented with a handsome club bag.

Mr. Rose has been for many years chief engineer of the Lovell & Christmas cold storage plant but has now severed his connection in Montreal to accept the position of mechanical superintendent of The Thomas Gold Mines Co., South Porcupine. In a few words which were heartily endorsed by all the members present, A. Hall, acting on behalf of the president, made the presentation and wished Mr. Rose bon voyage, assuring him that the Association would welcome his return at any time, providing he brought the bag with him filled with nuggets.

Mr. Rose leaves Montreal with the best wishes of all the stationary engineers who ever came in contact with him, and particularly the members of the Montreal & District Engineers Association, as the financial affairs of the association were never in a more promising condition as a result of his careful and energetic handling of same.

Convention Notes

The National Exposition of Power and Mechanical Engineering, to be held at the Grand Central Palace, New York, from Monday, Dec. 3, through Saturday, Dec. 8, is planned in co-operation with the national societies interested in the economy of fuel and in the production and use of power.

The Exposition will parallel the annual meeting of The American Society of Mechanical Engineers, which will be held at the Engineering Societies Building, 29 West 39th Street, the first four days of the week.

To avoid conflict between the two events, the sessions of interest to those who will attend the power exposition have been set for the mornings of the meeting and the exposition will not open until one o'clock each day. This arrangement will give engineers an opportunity to enjoy both events to the greatest possible degree.

Some of the subjects to be discussed at the Annual Meeting of the A.S.M.E. are: Heat Transfer for Fluids Flowing Inside Pipes, by Wm. H. McAdams and T. H. Frost; A Steam Loss Prevention Plan in a Textile Finishing Plant, by Henry M. Burke; A Graphical Study of Journal Lubrication, by H. A. S. Howarth. Factors in the Spontaneous Combustion of Coal, by O. P. Hood; Economic Phases of Coal Storage, by F. G. Tryon; Coal Handling and Coal Storage, by H. E. Birch and H. V. Coes; Economy Characteristics of Stage Feed Water Heating by Extraction, by E. H. Brown and M. K. Drewry; High Pressure, Reheating and Regenerating for Steam Power Plants, by C. F. Hirschfeld and F. O. Ellenwood; Reheating in Central Stations, W. J. Wohlenberg; Margins of Improvements in Central Station Steam Plant, by E. L. Robinson; Boiler Plant Economics by N. E. Funk and F. C. Ralston; Economic Status of the Oil Engine, by L. H. Morrison; Salt Velocity Method of Measuring Water, C. M. Allen and E. A. Taylor; The Gibson Method and Apparatus for Measuring the Flow of Water in Closed Conduits as Applied in Testing the Efficiencies of Water Wheels in Hydro-Electric Power Plants, by N. R. Gibson.

GOLDIE & McCULLOCH AND BABCOCK WILCOX IN MERGER

Announcement is made that a new company has acquired the manufacturing business of the Goldie & McCulloch Co., with the exception of that section engaged in the production of safes and vaults. The new organization is known as the Babcock & Wilcox and Goldie & McCulloch Co.

The head office and plant will be located in Galt, with R. O. McCulloch as president, A. R. Goldie, vice-president, and A. G. Pratt, vice-president of the Babcock & Wilcox Co., New York, as chairman of the board. Thus two prominent concerns have joined forces for the production of boilers, engines, pumps and other engineering equipment.

The Goldie & McCulloch Co. are one of the oldest firms in Canada, having been organized as a joint stock company in 1891, but, as a firm, it was founded in 1859 by the fathers of the president and vice-president of the new company.

R. Potter, Matheson, Ont., is having plans prepared for rebuilding a sawmill recently destroyed by fire, and is in the market for a steam power plant, etc.

Power Notes

The city of Belleville contemplates the erection of a pump house and the installation of a gasoline-driven fire pump of about 3,000,000 gallons' capacity. Estimated cost, $25 000. Gore, Nasmith and Storrie, Confederation Life Bldg., Toronto, engineers.

The Port Arthur Arena Co. contemplate the erection of a skating arena, including steam heating system. Estimated cost, $150 000. C. D. Howe & Co., Port Arthur, engineers.

The Town Council, Port Colborne, Ont., contemplate the erection of a $90,000 waterworks plant, including storage basin, pump house, two 750-gal. motor-driven pumps, one 1,500-gal. gasoline-driven pump, three pressure filter units, 12-in. main and 2,000,000-gal. elevated tank. H. Darling, Home Bank Bldg., Hamilton, mgr.

L. N. Huard, 129 Commerciale St., Levis, Que., plans the development of 17,000 h.p. on the River Megiscane, Temiscamingue County, and the erection of a $2,000,000 pulp and newsprint mill.

Tilson Co., Tillsonburg, Ont., are receiving prices and information on a $15,000 steam heating system to be installed this fall. Purchasing agent, E. V. Tilson, Tillsonburg.

The Foundation Co., 233 Broadway, New York, have been awarded the general contract by the Southern Canada Power Co. for a concrete dam and power house in connection with a 2 500,000 power development (approximately 30,000 h.p.) 3 miles from Drummondville, Que., on the St. Francis River.

Canadian Vickers, Ltd., Montreal, have been awarded the contract for one 4,000 h.p. turbine, 360 r.p.m., 64 ft. heading in connection with Portneuf hydro-electric development.

Silverwoods Ltd., London, contemplate the installation of a cold storage plant and equipment for the manufacture of ice cream at Lucknow. Estimated cost $35,000.

Canadian Vickers, Ltd., Montreal, have been awarded the contract for turbines and governors by the city of Winnipeg for a plant at Point du Bois at a cost of $18,800. Swedish General Electric Ltd., Toronto, received the contract for alternators, at $213,000, together with an order totalling $5,275 for spare parts.

The Gates Engineering Company, Montreal, have completed the installation of three 150 h.p.—H. R. T. boilers equipped with their furnaces for burning waste fuels in the Knox Bros. mills at Bickerdike Pier, Montreal. The above company have also been awarded the contract for the installation of four 150 h.p.—H.R.T. boilers to be installed in the new court house.

The Township of Etobicoke contemplates extensions to the hydro-electric power lines near Islington at an expenditure of $40,000.

The work is to be done by day labor; engineer N. McNicol; Clk., S. Barratt.

E. V. Buchanan, manager of the Utilities Commission, Hydro Offices, London, is having plans prepared for remodeling the main substation and installing additional equipment. At an estimated cost of $30,000.

The Canadian Packing Co., 3 Bathurst St., Toronto, is in the market for cold storage equipment, boilers, pumps, motors, etc., for a proposed meat packing house, including steam heating system, to be erected at an estimated cost of $1,000,000. Engineer or architect has not been selected.

The Queen's Hotel, Montreal, J. A. Raymond, Mgr , contemplates the erection of a ten story addition at an approximate cost of $500,000. Engineer or architect not selected.

The Hydro Electric Commission, Yonge and Shuter Sts., Toronto, is in the market for substation equipment, lines and service transformers, oil switches, switches and meters, for a proposed sub-station to be erected on Danforth Ave. Estimated cost $150,000.

The Mental Hospital, Essondale, B.C., contemplates the installation of a modern central heating plant. Tenders will be called by the provincial government.

The North Shore Power Company, Quebec, has obtained the lease of the *Chute de la Cheminee* on the Batiscan river and will probably construct a dam.

The Canadian Heating Apparatus Foundry Ltd., Montmagny, Que., has been incorporated with an authorized capital of $200,000.

The Richwell Brush Co. are establishing a plant in New Westminster for the manufacture of wire and fibre brushes.

The Canadian Ingot and Iron Co. are establishing a plant in Vancouver.

W. H. Yates, Hamilton, has been awarded the contract for the construction of a Hydro-Electric substation at Ottawa St. and Beach Road. Estimated cost $40,000.

The Back River Power Co., 35 Common St., Montreal, have started work on a $7,000,000 power development at Rivieres Des Prairies, Que. Preliminary work is being done by William I. Bishop, 10 Cathcart St., Montreal.

U.C.C. of E. Notes

Officers and members of the Universal Craftsmen Council of Engineers of Hamilton on Oct. 23, entertained a number of engineers from Canada council No.27, Toronto. Worthy Chief Alex. Leckie was in charge and short speeches were delivered by Past-President W. C. Terry and Worthy Chief Holmes. At the next regular meeting papers will be presented by two prominent engineers in the refrigerating profession.

Obituary

Statement by B. G. Lamme, Chief Engineer of the Westinghouse Electric & Manufacturing Company, upon the death of Dr. Charles P. Steinmetz, consulting engineer of the General Electric Company:

"I deeply regret the loss of Dr. Steinmetz as a personal friend and because his death means the passing of a brilliant analytical engineer. He was a very able man, who contributed much to the electrical industry, which will mourn his passing.

"As a personal friend, I knew him to be a witty, sociable man, quite human in his dealings with his fellow men. The public, to which he was known as a man of mystery, would have found, as I did in personal contact, a real human being.

"Dr. Steinmetz and I entered the electrical business within a month of each other in 1889. He was associated with the Eickomyer Company of New York for several years after he first came to this country. In this time his writings on engineering subjects attracted much attention in electrical circles and he soon joined the General Electric Company.

"He entered the electrical industry at the start of what engineers call the analytical period, when mathematical analysis took the place of 'cut and try' experiment. His greatest fame was achieved during this period of rapid electrical expansion, during which he contributed greatly to scientific analysis of electrical phenomena.

"Unlike many brilliant engineers, he left a record of his work in his numerous writings, so that his contributions to science will live in engineering journals. He was a prolific writer on diversified subjects and his keen mind was no more clearly displayed anywhere than in his contributions to scientific journals.

"Dr. Steinmetz will always be remembered in the electrical industry, and I will always remember my personal contact with this very able man."

Leonard Palin McClelland, divisional superintendent of the metropolitan division of the Hydro-electric Railways, died Oct. 29, at his home, 121 Eglinton Ave., Toronto, after a six months' illness. Mr. McClelland was one of the best known railway men in the city, having been connected with the old Toronto Street Railway, the Scarboro division of the Toronto and York Radial Railway, and later with the Metropolitan.

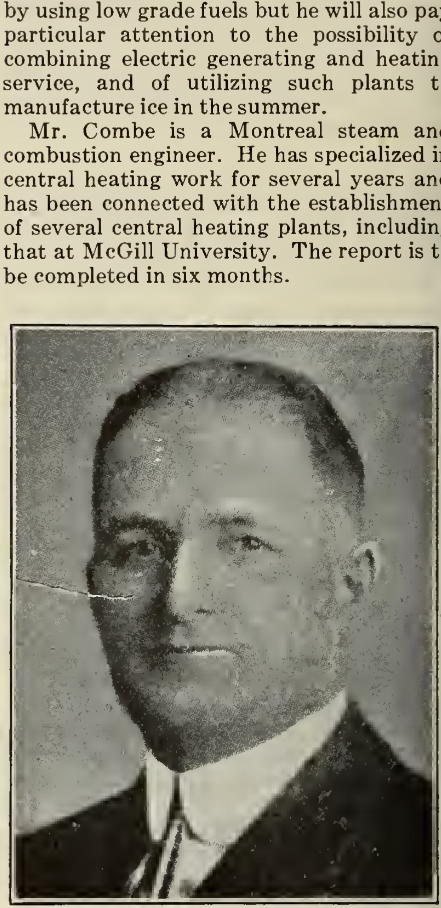
Personals

Thos. Rusk, recently of Hamilton, has taken charge as Chief Engineer of the Fort William Paper Co's. plant at Fort William.

Prof. C. R. Young, chairman of the Toronto Branch of the Engineering Institute of Canada, gave an interesting address in the Mining Building of the University of Toronto, Oct. 18, on "The Rise of the Engineer."

F. A. Combe, chairman of the fuel committee of the Engineering Institute of Canada, has been appointed by the Federal government to make an exhaustive report on the feasibility of establishing central heating plants in Canada as a fuel economy measure. Mr. Combe will not only investigate the saving that can be effected by using low grade fuels but he will also pay particular attention to the possibility of combining electric generating and heating service, and of utilizing such plants to manufacture ice in the summer.

Mr. Combe is a Montreal steam and combustion engineer. He has specialized in central heating work for several years and has been connected with the establishment of several central heating plants, including that at McGill University. The report is to be completed in six months.



R. MANLY ORR.

R. Manly Orr, chief engineer, Pacific Coast Pipe Co., Vancouver, had charge of the power plant of the Adams Wagon Co. at Brantford for nine years, leaving there for the west so that he might be near his aged father. Mr. Orr has been in his present position for eleven years and in 1922 had the honor of occupying the pulpit 63 times in greater Vancouver and district—his activities in religious circles taking him into 21 different churches of five denominations in the year.

Mr. Orr, a firm booster of "Power House," is proud of his profession as he believes no man can be an engineer who is not a student and thinker. Commenting on the biography of John Quinlan, "on the job," in the Sept. 20 Power House, Mr. Orr says Mr. Quinlan's genial smile bounded by the oil can, pipe wrench, overalls and factory fence, is a sermon in itself.

"It is the living demonstration of a great truth, that honest toil is a wholesome thing, neither killing the smile on a man's face nor souring his life."

The Sisters of the Holy Name of Jesus, Notre Dame St., E., Montreal, contemplate the erection of a five story mother house on Maplewood Ave. Estimated cost $600,000. S. Duchostel, Outremont, Engineer.

Progress in New Power Equipment

PIPE CUTTING MACHINE

A NEW machine, to meet a long-felt want in the pipe cutting and threading field, has been placed on the market by the Williams Tool Corporation, of Brantford. This machine has been designed to fill the gap that has long existed between the heavy and immobile power machine and the light hand threading and cutting equipment. It is called a Portable Pipe Cutting, Threading and Reaming Machine.

The manufacturers point out that the machine weighs less than 500 pounds and may be dismantled in less than three minutes and there is every indication that it will have an extensive sale to steam fitters, manufacturers and engineering concerns who do not require the heavy machine but have found their equipment inadequate for rapid and efficient service.

Portable and Demountable

It is perfectly designed, for weight and strength, to cut smooth and clean threads, either right or left hand, within its capacity, and can be dismantled in two minutes and fifteen seconds.

The small oil trough or cutting box under the carriage lifts off, allowing the carriage and head to slide off the round ways and by releasing two screws the Shelby tube steel ways can be pulled out of the head stock, thus leaving only the pedestal and head stock as a unit which two men can easily lift.

Its capacity is as follows: Threading, pipe ¼ to 2 in. inclusive, bolts ⅜ to 1¼ in.; cut-off, pipe or tubes ¼ to 2 in. inclusive, bolts and rods ⅜ to 1½ in.; reaming inside or chamfering outside, pipe or tubes ¼ to 2 in.; longest running thread at one chucking 10½ in.

Motor Belt and Hand Driven

The machine is driven by a standard ¾-h.p. motor by means of belt from motor to drive pulley enclosed in the base of machine and mounted on a hinged table which allows tightening of the belt instantly by screwing down on a thumb screw. Current is supplied from an ordinary lamp socket through a standard cord with push socket. A button control switch for start and stop is mounted on the machine at the operator's left hand.

Since the drive from motor to machine is through a belt, this insures protection to the dies and other working parts should excessive strain be placed on any part of the machine. The slippage of belt in this case would act as a safety factor.

The machine can be converted to belt drive by simply taking off the motor belt and driving from a line or counter-shaft.

Provision has also been made to operate the machine by hand. To do so, it is only necessary to shift gears to neutral position when the crank handle can be fitted on to the worm shaft which is directly connected to the spindle through worm and worm wheel.

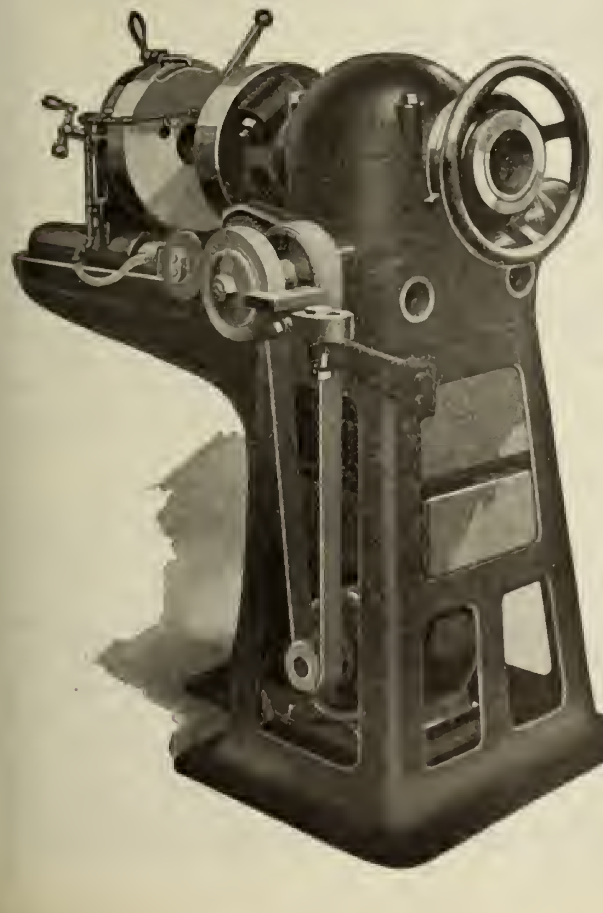
Two Speeds

The spindle has two speeds arranged similar to automobile sliding gear, which also gives a neutral position for the purpose of starting and stopping spindle without shutting off current. It is operated by small knurled push button at operator's left hand.

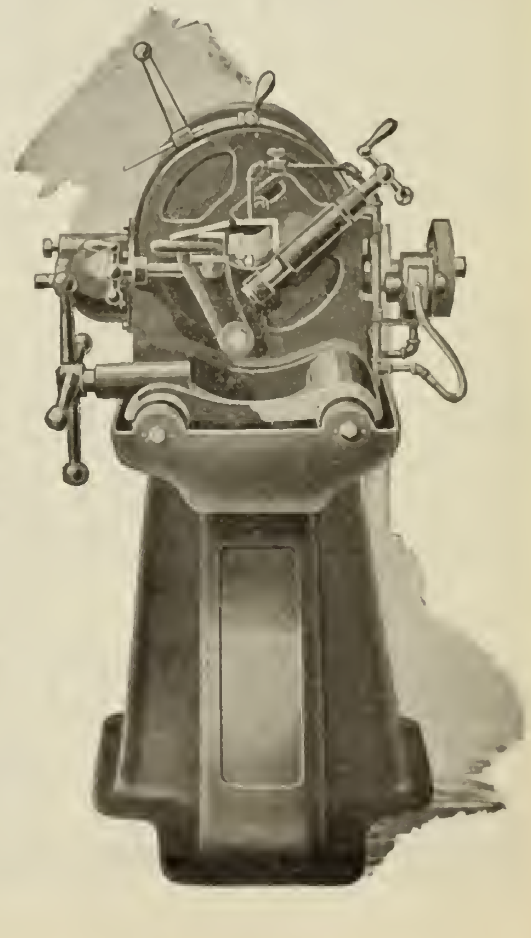
All gears are made of steel, machine cut. Sliding gear driven by standard Woodruff keys. The drive to spindle is through a quadruple worm and worm wheel with ball thrust. All gears and worm are lubricated by oil from a special oil sump.

All bearings in the machine are equipped with standard Bunting bronze bushings, lubricated from a special oil sump. The driving shaft has three bearings and the worm shaft two.

The spindle is made of standard Shelby steel tubing, extra heavy, and has a bore of 2⅞ in. which allows a 2-in. coupling to pass through. The spindle rests in a box type head stock which has



Two views of the Portable Pipe Cutting, Threading and Reaming Machine placed on the market by the Williams Tool Corporation of Brantford.



wide face bearings lubricated by splash system from special oil sump.

The front gripping or driving chuck is Williams standard three-jaw universal self centring. The chuck worm and worm wheel are steel packed in grease, while the chuck jaws are tool steel tempered. On the rear of the spindle is a standard Williams three-jaw self-centring scroll chuck for centring long lengths of pipe and operated by a hand wheel.

The carriage ways on which the carriage slides are standard Shelby steel tubing, extra heavy, accurately sized to one-thousandth part of an inch and highly polished, thus insuring a long wearing surface.

Die Head

The die head and carriage are cast in one piece, thus eliminating any possible chance of the head getting out of alignment. The part of the carriage resting on the Shelby tube ways is babbitted with extra hard babbitt.

The carriage has six bearing parts on the ways, three on each side. This makes it possible for the carriage to be re-babbitted and lined up at little expense after years of hard usage. Operation of head and setting of dies is very much similar to that used on all the standard machines.

The dies are operated by cam and lever and are interchangeable, adjusted to all variations of fittings. A graduated die head makes unnecessary the use of blank gages for setting the dies. Whenever several pieces of the same size pipe are to be cut, a cam stop is used to stop the cam lever at the right place for that particular size.

Three sets of dies are furnished with the machine as standard equipment, one set cutting ¼ and ⅜, one set ½ and ¾, and one set 1 to 2 in.

To change the dies it is only necessary to slack off two nuts on the face of the die head, when the die plate can be shifted a fraction and lifted right away from the head.

Cut Off and Ream

The cut-off attachment is mounted on the rear of the die head and is operated by a screw and hand wheel. A quick-operated V slide steadies pipe when cutting off. The V slide is equipped with hardened tool steel facings insuring a lasting wearing surface on the steady rest. This enables the operator to cut all sizes of pipe and bolts as required.

The blade is double bevel high-speed, set at an angle, which means that the machine can be run at its highest speed for all cutting-off purposes.

On the cutting-off attachment is pivoted the reamer holder operated by a lever. It is so arranged that all sizes of pipe can be reamed inside, or if necessary a slight chamfer can be made on the outside.

The tool bit used for this purpose is ⅜ in. square, the same as used in any standard tool holder.

A Brown & Sharpe rotary geared oil pump is located on the rear side of the machine near the driving pulley. It is gear driven direct from the intermediate shaft. All gears are enclosed in a gear case. The oil is pumped from the reservoir in the base of the machine through a specially constructed strainer to the pump. From there it is forced through a flexible hose to the die head, thus insuring an ample supply of cutting oil to the dies and cut-off tool when operating.

A small independent valve is provided for each operation.

After flushing the dies and cut-off tool, the oil drains back into the small oil pan under die head. Before leaving the pan it is strained, after which it flows back into the reservoir and is used over continuously. But each time it must pass through the strainer in the oil pan, and the fine strainer on the end of the suction pipe eliminates any possible chance of grit or dirt getting into the pump.

Place to Store Dies

A special die cabinet is cast in the top of the pedestal, providing a safe and convenient place to store dies as well as any small tools used on this machine.

Each part used on this machine has been manufactured from specially designed jigs and fixtures which insure all parts being accurately machined and interchangeable.

Emery Wheel Special Feature

An outstanding feature of this portable threading machine is a high-speed emery wheel which is driven from a pulley shaft at the back of the machine.

Every user of a pipe machine has long felt the want of a small emery stone, for in every shop there comes a time when it is necessary to touch up a die, sharpen a chisel or take a burr off some tool, and in designing this portable pipe machine, the manufacturers had in mind the purchasers' requirements in this connection as well as a high-class pipe machine.

This emery wheel is driven from the pulley shaft at approximately 1,000 r.p.m. and the machine is so designed that when the operator desires to use the emery stone the gears on this shaft can be thrown into neutral and no other part of the machine is running except the motor and emery wheel which allows him full use of the motor horse power for grinding purposes.

Of Norton Manufacture

The stone is of Norton manufacture, 5¾ in. diameter, ¾ in. face and proper grade for general grinding purposes. The shaft carrying the stone is of extra large diameter and equipped with three Bunting bronze bushings with all the bearings running in oil.

STEAM QUALITY

(Continued from page 33)

In the operation of the throttling calorimeter, it is assumed that no heat is lost. Therefore, the total heat content of the wet high pressure steam is taken as equal to the total heat content of the superheated low pressure steam. If the quality of the steam is represented by X, then the total heat in one pound of wet steam will be represented by h + XL, where h represents the "heat of the liquid," and L represents the "Latent heat" at main steam pressure. These are found from the steam tables. The total heat as expressed above is equal to the total heat in one pound of the low pressure superheated steam which is expressed by the formula H + 0.48(T — t) where H represents the total heat of a pound of saturated steam at exhaust pressure; 0.48 is the specific heat of superheated steam, or the amount of heat required to raise one pound of superheated steam through one degree Fahr.; T represents the temperature read on the thermometer in the exhaust chamber of the calorimeter; and t is the temperature of saturated steam at exhaust pressure. H and t can be found from the steam tables, or, if exhausting at atmospheric pressure, t may be taken as 212 degrees.

Therefore $h + XL = H + 0.48\ (T - t)$

$$\text{or } X = \frac{H + 0.48\ (T - t) - h}{L}$$

Example:—Let us suppose that thermometer at the inlet reads 361 deg. From the steam tables we find h = 332.9 and L = 861. The temperature in the low pressure side is 233 deg., and the pressure in the gauge is 1.3 pounds gauge, or 16 pounds per square inch absolute, then t = 216.3, and H = 1,152.

$$X = \frac{1152 + 0.48(233 - 216.3) - 332.9}{861}$$

$$= \frac{1152 + 0.48 \times .16.7 - 332.9}{861}$$

$$= \frac{1152 + 8 - 332.9}{861} = \frac{827.1}{861} = .967$$

Thus the quality of this steam is .967, or 96.97 per cent., or 3.3 per cent. wet.

Obviously this type of calorimeter is suitable only when there is enough heat available to evaporate all the moisture present. It is found, by experience, that with more than 5 per cent. moisture this calorimeter is inaccurate, and with low initial pressure even less moisture than this makes the instrument inoperative.

ERECTING DIESELS

In erecting a Diesel,engine the foundation should be thoroughly reinforced with old rails, reinforced bars, etc. The best concrete mixture depends on the character of the sand and gravel. A ratio of 1 part cement, 2½ parts sand and 3 parts crushed rock or gravel is well balanced. The concrete should not be too wet. It should not be rammed to any great extent. A rod should be used to push the concrete into the corners, etc. After finishing the concrete, the foundation should stand at least ten days to ripen. During this process the surface is best covered with wet sand.

DON'T TREAT A LUMP OF COAL WITH CONTEMPT!

(Continued from page 26)

cinders. Their business is primarily the manufacture and sale of gas, a fuel from which heat is most readily available.

They desire to be free from the production and sale of a solid fuel which complicates their plant and puts them in a business of larger dollars and cents annual turnover than their gas business. Their problem would be much easier if the general public knew more concerning the use of fuels and this is where the Engineering Institute of Canada has undertaken to help a little through its fuel committees.

A great deal of work has been and is being done on the development of a process for the complete gasification of coal. All the processes reported on are in the experimental stage and it is not possible to predict from the data available when any of them will become a commercial success.

At the same time a cheap way to prepare the gas from high sulphur coals is being sought with partial success in some of the larger plants. Much interesting and valuable research can be and should be begun and encouraged along this line.

In connection with coal itself recent investigations show that the distribution of organic sulphur on the vertical span of a coal bed is quite uniform. On the other hand intense irregularity of distribution is characteristic of the pyritic sulphur in coal. This offers a possibility of securing a low sulphur product by separate mining of parts of the seam.

Analyses of typical gas coals show roughly:

	U.S.	Cape Breton
Moisture	2%	2%
Volatile Matter	38%	37%
Fixed Carbon..	55%	55%
Ash	5%	6%
Sulphur	0.6–1.25%	1.8–2.2%

In general the thermal efficiency of a gas plant may be conservatively considered as 75 per cent., some approach 80 per cent.

Average Efficiency

A ton of coal treated in the gas works will produce 11,000 cubic feet of gas containing 520 British heat units per cubic foot or a total of 5,720,000 heat units. Assuming that the average efficiency in the consumption of coal is 30 per cent. and that the original coal contains 13,500 heat units per pound, the quantity of useful heat from a ton of coal is then 5,100,000 units, a quantity less than that in the gas which might have been obtained from the raw coal.

In modern coke oven practice the aim is to obtain as much coke as possible from a ton of coal. Because most of it is used for metallurgical purposes where it is required to support heavy weights during all the time in which it is being consumed, such coke must be able to resist crushing at the same time as it burns readily. For best results the coke should be capable of being broken into large lumps approximating cubes. Coals extremely high in volatile matter may produce excellent results in gas works from which the coke is used for a different purpose. In coke ovens they will usually give a coke which breaks into needle-shaped lumps which are not desirable. Coals too low in volatile matter may produce no coherent coke at all.

As a general thing coals containing 16 to 40 per cent. of volatile matter can be coked but coke oven practice demands 18 to 33 per cent. Two coals, one high in volatile matter and the other low, neither of which will produce a good coke when alone, may give an excellent coke when intimately mixed.

Limit Retort Sizes

In gas works the aim is to produce gas and some of the residual coke is consumed to provide the necessary heat. At the coke oven the opposite holds. Coke is desired, gas is not, therefore some of the gas produced is burned to supply the heat. Perhaps 50 to 60 per cent. of the gas is consumed in this way while the remainder is available for any purpose to which it can be adapted.

The chief difference between the method of carbonizing in the coke ovens and in the gas works is in the size of the unit in which the coal is treated. In the gas works the retorts are of limited size, holding from 400 to 2,000 pounds which is exposed to the heat during six to eighteen hours; at the coke ovens the oven is of comparatively unlimited size holding from five to twenty tons, which is heated during period of from 18 to 72 hours.

At the same time as he produces a strong suitably sized coke the engineer is faced by the fact that he must have it low in sulphur and ash. To secure this he purchases only such coal as is naturally comparatively free from these evils, then he attempts their further reduction by crushing and washing it. Depending upon the condition of the coal and distribution of the sulphur a reduction of from 40 to 50 per cent. in the ash and 15 per cent. in the sulphur may be obtained. His objective is to keep the quantity of sulphur in his coke down below 1.25 per cent.

Enough has been said to show that in gas works and coke ovens the kinds of coal carbonized must be of the very finest quality, and consequently must of necessity be the most expensive. For gas works and coke ovens of this continent an enormous quantity of coal is needed every year.

Those who know are uttering a continuous warning that the supply is not inexhaustible. Their percentage of sulphur more than their percentage of ash is the factor which shuts out cheaper coal from these industries. It is obvious then that those who search for a way to eliminate the troubles of sulphur from the carbonization of coal and the manufacture of gas deserve international recognition, support and reward.

Lack of Volatile Matter

Probably the chief distinctions between coal and coke are the almost entire lack of volatile matter in the latter and its porous structure, which qualities enable it to be consumed in a single stage and at a high temperature to carbon dioxide.

Chemically considered, coke consists of the carbon together with all the mineral constituents of the coal from which it is made. It contains only a trace of hydrogen. The amount of carbon varies from 85 to 90 per cent. and the ash from 5 to 15 per cent.

When fired in furnaces under correct conditions of balanced draft, the formation of carbon monoxide can be largely avoided. The admission of secondary air is therefore unnecessary; and this fact permits the minimum of suction or chimney draught being maintained over the fire, the whole of the air necessary for combustion being taken under the fuel bed. The inleakage of air through faulty boiler brickwork and economizer settings, also the by-passing and short-circuiting of hot gases, may thus be reduced to a minimum. With coke fired on these lines experience has proven that efficient combustion and a high calorific intensity are much easier to secure than in the case of coal firing.

That coke has a higher calorific intensity than coal—which is not inferable from its analysis—is evidenced by the fact that it is used for metal-melting and other high temperature processes. The explanation probably is that the process of combustion being already far advanced by the heat absorbing process of distillation, less heat is required to gasify it than is necessary in the case of coal. Also the quantity of heat which is required to raise the temperature of one pound of coke through one degree is less than that required for coal.

This last statement gives the reason that coke does not have the chilling effect of fresh coal when thrown upon an incandescent fire. In addition, as hydrogen is almost entirely absent there is no formation of water with its accompanying loss of heat which deprives coal of four and a half per cent. of its original heating value.

A Fair Output

Recent tests show that an evaporation of seven to eight and a half pounds of water per pound of run-of-oven gas coke may be considered a fair output to be attained in practice with the same degree of care as is generally met with in good hand-fired boiler-room operation.

For a considerable time much difficulty was experienced in adapting coke to effective use with automatic chain-grate stokers. This has now been overcome by the "Sandwich" system of blending coal and coke, invented by E. W. L. Nicol, engineer of the London Coke Committee, London, England.

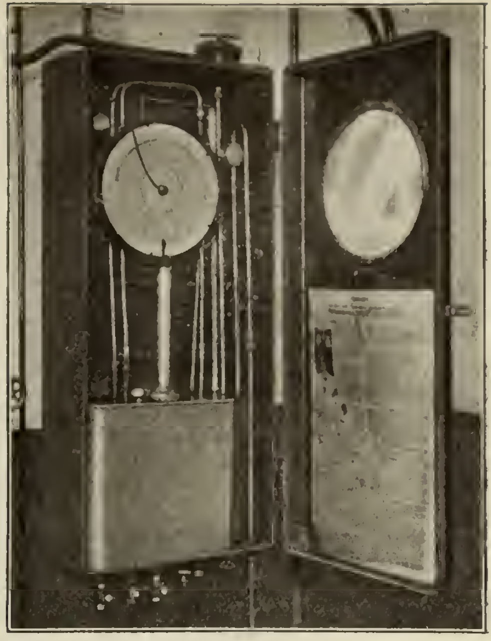
The fuel is fed to the grate in such a way that the coke is between two much thinner layers of a poor grade of coal.

Amongst the solid fuels in use coke has no equal for cleanliness. None other can equal it in rapidity of response to any change in the conditions of draught.

Last winter the British Empire Steel Corporation found no difficulty in selling its surplus of coke, about 6,000 tons per month, to consumers in the Maritime Provinces. During the month after the first appearance of the Besco product in Halifax the sales of coke jumped from 400 to 2,000 tons, good evidence of its popularity. This year a still larger quantity will be consumed if it can be obtained. Used properly it is giving value ton for ton equal to hard coal and there is usually a considerable price differential in favor of the ton of coke.

When coal is used for steam-raising under the best known conditions, it is

FOXBORO
Two-Pen Recording Thermometer



FOXBORO
Recording Gauge

Judge an Instrument by its Records

We'd like to have you judge Foxboro Instruments by their records.

The Foxboro-Heath CO_2 Recorder, for example, produces reliable records year after year. It has only three moving parts and is of all metal construction, no glass to break or rubber to leak.

Judge this instrument by the record in the right hand margin.

The Foxboro Recording Thermometer and Recording Gauge are as dependable. The new, improved helical tube movement that is permanent in calibration and capable of years of severe service without loss of accuracy is the reason for their dependability.

Let us send you Foxboro Bulletins CF-114 and CF-104-1.

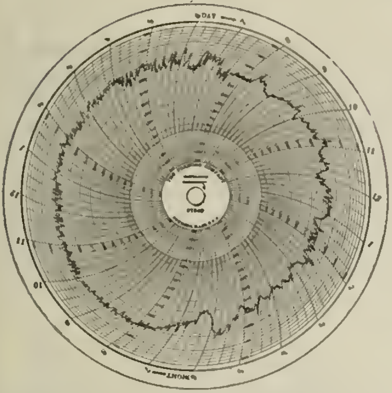
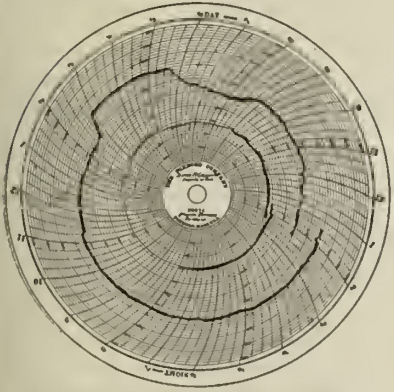
THE COMPASS OF INDUSTRY

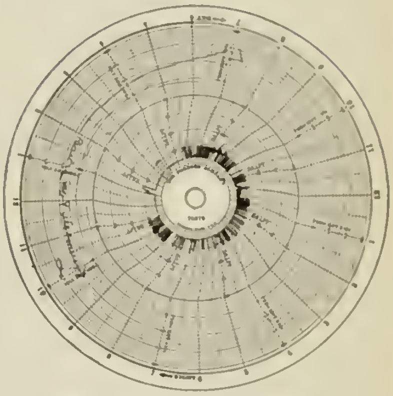


Record of feed water temperature made by a Foxboro Recording Thermometer in a textile mill power plant. Load variations during the day and uniformity of load at night are plainly shown.

The fidelity with which the slightest temperature variations are recorded is characteristic of all Foxboro charts.



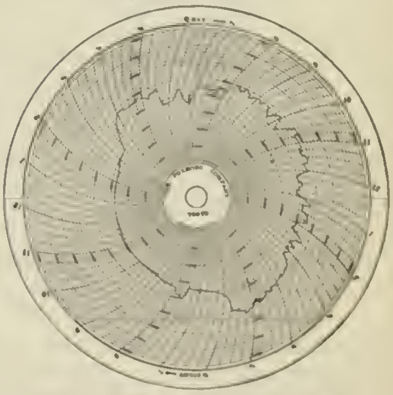
Record of inlet and discharge water temperature of a condenser at the Atlantic Refining Co., provides a positive check on condenser operation, insuring high vacuum and increased efficiency.



Combined CO_2 and draft record made at the plant of the City of Norwich, Conn.

The chart is an example of how well combustion can be controlled with the Foxboro chart as a guide. During the load period CO_2 is maintained at from 13 to 15%.

Note how quickly the CO_2 picks up when the load is put on the boiler in the morning.



Record of flue gas temperature made at the National Blank Book Co.'s Plant, Holyoke, Mass.

The even maintenance of temperature between 400 and 500 degrees Fht. during the load period indicates that very little heat is wasted up the stack in this plant.

obvious that there is little to be gained by any preliminary sorting of the thermal units of the coal into fuels of higher availability such as gas and coke. It is well known that an efficiency of 75 to 80 per cent. is attainable in steady practice. But best known conditions pertain to only five per cent. of the steam plants in the country. An increase of ten per cent. in overall efficiencies of the remaining 95 per cent. would reduce the national coal bill $9,000,000 per year.

Domestic purposes account for the use of one-fifth of the annual national consumption. For 1922 the actual figures would be one-fifth of 31 million tons, 6.2 million tons. If we compare a liberal household efficiency of 35 per cent. with the average efficiency of the best steam plants we at once see the extravagance of the waste involved in such use of coal.

In this Dominion, often spoken of as containing unlimited resources, we are inclined to take things as they come and not look too far into the future. The position of Central Canada in relation to her fuel supply should awaken us to added interest in and support of research which will bring curtailment of our wastefulness. Due to the transportation distances the present problem is, and the future problem will be, one of utilization. Certainly the people in the central provinces are the ones most vitally interested and it is to be expected that they will take the lead in the technical and economic solution of their difficulties, invoking the assistance of new legislation if necessary.

Contain Population

Those provinces contain the bulk of Canada's population and manufacturing plants, therefore, they will benefit most from any savings which can be accomplished. We can learn many lessons in the economic use of domestic fuel from countries like Norway and Sweden which must import from foreign countries the bulk of their coal and coke.

When we consider the number of combinations which are possible of different primary products, if the temperature and pressure can be varied it is obvious that a great amount of work can be done usefully in following up the distillation of coal.

Great progress may be expected along these lines and greater developments than any heretofore accomplished. For the present let us assist the national welfare by advocating the wider use of those fuels derived from a lump of coal by distillation for reasons of economy, efficiency, expediency and hygiene.

FACTS YOU SHOULD KNOW ABOUT STEAM GENERATION

(Continued from page 29)

865 B.t.u. and $q_1 = 330$ B.t.u. From data given above—$r_2 = 972$ B.t.u. and $q_2 = 180$ B.t.u. From the thermometer reading ts = 262 deg. Substituting these values in the formula and solving, we have

$$x = \frac{972 + 180 + 0.47(262 - 212) - 330}{865} =$$

0.965 or 96.5%. That is, the steam contains 100—96.5 = 3.5% of moisture.

When the amount of entrained moisture exceeds the limits of the throttling calorimeter, the separating calorimeter should be used. This is shown in section in Figure 5 and is in effect a small separator which mechanically separates the entrained water from the steam and collects it in a reservoir "A," where its weight may be indicated by a graduated gage glass. or it may be drawn off and weighed. The weight of dry steam passing from the calorimeter in a given time through the orifice "B" may be determined by knowing the area of the orifice and the pressure in the chamber "C."

This type of instrument is often provided with a pressure gage graduate to show the weight of steam passing through the orifice in pounds per unit of time. Knowing the weight of water collected in the reservoir in a given time, and the rate of steam flow through the orifice, it is a simple matter to compute the quality of the steam.

HOW TO REPAIR ELECTRICAL INSTRUMENTS

(Continued from page 31)

5.268 Mmg. for 360 degrees, and these are the terms in which the spring should be ordered from the manufacturer.

If it is desired to increase the instrument capacity 100 per cent. then springs one-half as strong or 2.635 Mmg. should be ordered or if it is desired to decrease the capacity to one-half, then springs twice as strong or 10.536 Mmg. should be obtained.

This discussion of course refers only to instruments in which torque is proportional to the current or voltage applied. If a dynamometer type meter is used, the torque increases as the square of the current or voltage and in changing the capacity, the torque at the desired current or voltage calculated.

For instance, if we have a five ampere induction type instrument and wish to change the full scale capacity to six amperes due to an increase in load, assume that the full scale torque (300 degrees) is 12 Mmg., then the torque at five amperes, would be

$$(5)^2 : (6)^2 = 12 : X$$

Solving this would give 17.3 Mmg. But this is for 300 degrees. Consequently the torque for one revolution, or 360 degrees, would be

$$300 : 360 = 17.3 : X$$

Solving this, would give 20.7 Mmg., which is the strength of spring to be ordered from the factory.

Rewind Main Coil

Care must be taken in changing capacities that the winding is not overloaded. If great changes are to be made, the main coil should be rewound. When lowering a capacity, care must be taken not to put a very weak spring in the instrument as the friction may cause very unsatisfactory results.

In actual operating practice there are two kinds of errors in any instrument; first, errors of observation due to parallax, width of divisions, etc., which are a percentage of the full scale and independent load; second, errors caused by calibration or effects which vary the constants of the instruments, which are percentages of the actual readings.

For simplicity, however, the accuracy at all points of the scale of electrical instruments is stated merely as a percentage of full scale capacity; therefore, the percentage of reading error increases as the load is decreased.

Electrical measuring instruments are necessarily delicate mechanisms which require care in handling and correct installation to avoid damage and to obtain accurate and reliable results.

It is important, however, to distinguish between the qualities which produce the highest accuracy necessary in laboratory instruments and the quality of ruggedness which is of greater importance in switchboard instruments. For this service what is desired is not so much an instrument which is accurate within a fraction of a per cent. when installed, as one which will retain a fair degree of accuracy, as for example, within two per cent., indefinitely, an instrument which will withstand the conditions met with in service and one which can easily be repaired if damaged.

DIESEL OPERATION

Most Diesel engines run best with a clearance of 0.004 to 0.006 inch between the shaft and top bearing shell. This should be checked at intervals by means of lead wires placed on the shaft before the bearing cap is pulled down. It is necessary to draw the cap snug. Upon removal the thickness of the wire will indicate the clearance. If excessive, part of the shims should be removed. With pressure oiling systems the shims must fit the shaft very snugly at each end of the bearing.

DIESEL ENGINES

The distinguishing feature of the Diesel engine is that the air charge is compressed to a high pressure such that the resulting temperature of the air is above the self-ignition point of the fuel oil. As a consequence the oil when introduced into the cylinder is ignited by the high temperature. The fuel is introduced at such a rate that the pressure does not rise above the compression pressure.

Originally Dr. Diesel contemplated introducing the oil at a rate that allowed the heat created by the burning fuel to just equal the work done on the piston. If this had been possible, the temperature during combustion would have been constant. As it is, the temperature rises while the pressure is either constant or experiences a slight drop.

For this reason the Diesel engine is known as a constant pressure engine; i.e., heat admission at constant pressure. The exhaust or heat discharge is theoretically at constant volume, although part of the heat is thrown out during the exhaust stroke at constant pressure.

The Universal Oil Burner Co., Windsor, has been incorporated for $40,000 to manufacture oil burners, by Norman A. McLarty, Albert Eastman and Mary Cooke.

CLASSIFIED ADVERTISEMENTS

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads set in border, are at the card rates.

Every Engineer, Mechanic and Electrical Worker will welcome this new master set. It will answer your problems.

It will help you witb your daily work.—A sure source of advancement and higher pay. Complete up-to-date information that is thoroughly and easily explained on every branch of modern engineering and electrical practice.

POSITIONS WANTED

NIGHT ENGINEER WITH 3rd CLASS CERTIficate. Must be widower or bachelor and good worker. Apply Box 118, Power House.

BUSINESS CHANCES

SMALL BOILER REPAIR BUSINESS FOR SALE—with house property adjoining. No opposition. Located in a large manufacturing city. Reason for selling, owner in ill-health. Apply Box 110, Power House.

POWER PLANT FOR VILLAGE OF TIGNISH About 18 kil. hour capacity 110 to 220 volting alternating current. Apply to John A. Hackett, Box 67, Tignish, P. E. I.

PISTON RINGS

EVER-TYTE and ZELCO Piston Rings with Patented Zelco Process Save Gasoline, Oil, Increase Capacity, Prevent Cylinder from Wearing Out of Round, Lessen Carbon; after using, make arrangement with us to sell them; made up to 80-inch; used in Locomotives, Boats, Engines, Compressors, Ice Machines, Autos, Trucks, Tractors, etc.; are looking for distributors with mechanical knowledge; all or part time; real opportunity. Ever-Tyte, St. Louis, Mo.

EQUIPMENT FOR SALE

FOR SALE—ONE CANADIAN GENERAL belt driven, direct current generator, 115 to 125 volts, capacity 360 amperes, speed 975 R.P.M's.; also a quantity of used shafting and pulleys. Apply to Box, Power House.

SAW MILL MACHINERY FOR PORTABLE medium and heavy mills, band or circular; we build everything for the saw mill from haul-up to sorting table. The Waterous Engine Works, Ltd., Brantford.

TAYLOR SAFE FOR SALE—INSIDE DIMENsions 15" deep, 2 ft. 6" wide, 3 ft. 11½" high. We will accept $225.00 for this safe—a bargain for someone. Apply Box 110 Power House

For Quick Sale

Self-oiling high speed engine, single cylinder, 17 in. bore x 16 in. stroke Engine develops 200 H.P. when running at 235 R.P.M. with 100 lbs. steam pressure. There are two heavy leather belts 18 in. wide. The engine has two fly-wheels, each 78 in. diameter x 18 in. face. Apply Box 112, Power House.

FOR INSTANCE—

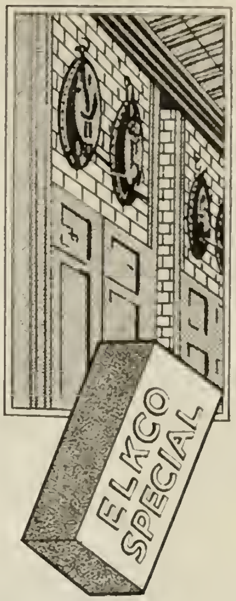
One large Canadian paper mill had this fire brick problem.

10 B and W boilers 500 H.P.; fired with fuel oil.

When this plant was built we recommended ELKO SPECIAL for this equipment.

They have had such complete satisfaction they have used ELK FIRE BRICK exclusively ever since.

This is only one little instance. Mill reference on request.



What's Your Problem?

SIL-O-CEL
It's Insulation that does it

A TINY FLAME keeps the Eskimo's igloo warm and comfortable, despite the fact that the outside temperature may be many degrees below zero.

It's insulation that does it. Millions of microscopic air cells formed between the particles of tightly packed snow break up heat penetration and hold it within the hut. Large air spaces are not as effective, as the U. S. Bureau of Standards have decisively proved, and the perfect heat insulation only needs in addition to its countless minute air cells, a composition which withstands high temperatures, and sufficient structural strength.

All these requirements are found in SIL-O-CEL Heat Insulation—in world-wide service on all types of high temperature equipment. Tests by the Bureau of Standards prove it to possess a lower heat conductivity than any other insulation suitable for high temperatures. Furnished in forms which withstand without shrinkage, direct heats of 2000° F., SIL-O-CEL has ample structural strength, is easily applied and permanently effective.

A type for application to boilers, furnaces, ovens, kilns and similar heated units without change in design — Brick, C-22, Block, C-3, Powder, Cement.

Write nearest office for complete information given in Bulletin W-6C, or mail the coupon.

A CORRECTION

The crushing strength of SIL-O-CEL Insulating Brick was incorrectly reported in last month's advertisement as being 400 lbs. per square foot. This should read "400 lbs. per square *inch*" or 28 tons per square foot.

Twelve Good Reasons Why You Should Use "SAFETY" PLASTIC METALLIC PACKING

In Bulk.

1—The ease and quickness with which it is used.
2—No waste—all remnants used.
3—Lasts fully ten times as long as Fibrous packing.
4—Costs only one-third as much as other metallic packing.
5—Does not soil machinery—no friction.
6—Stands any pressure.
7—Unaffected by heat or cold.
8—Requires little lubrication.
9—Never becomes too hard.
10—Requires no change of stuffing box—fills the packing place by pressure.
11—It's a natural lubricator—holds no moisture.
12—Can't wear a rod and put it "out of true."

Guaranteed to last three years without renewal.

Send for full particulars, also about our "Safety" Superheat Sheet Packing.

In Cotton Tubes.

Having Any Furnace Trouble

?

There's bound to be trouble in any furnace or fire-box soon after the edges of the brick start to disintegrate—it's the weakest spot. The only remedy is to eliminate all edges and build a one-piece lining with

STERNSON
No. 40 Monolith

A ceramic mixture of plastic and calcined refractories which can be molded into a jointless, gas-tight furnace or fire-box lining by inexperienced men. It is a positive protection up to 3,000 deg. F. as, when vitrified, it forms one great fire brick. The saving in price alone, compared with brick and mortar, is worth considering.

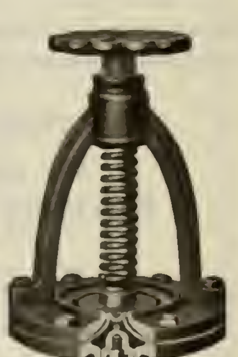
CURTIS ENGINEERING SPECIALTIES

Comprise a line of devices that have stood the test of years for the utmost in efficiency. They are built for dependable and enduring service. Scrupulous care in the selection of material and in construction, with adherence to the highest engineering standards, have won them a commanding position. The



CURTIS WATER-PRESSURE REGULATOR

will deliver water into service pipes at any desired pressure, regardless of any fluctuations of outside pressure.

Trouble with rust or clogging with sediment is prevented. Waste of water in domestic use by flying or spattering is avoided by the reduced pressure. This also prevents water hammer or concussion and prevents wear and tear on all packings and seats in valves and faucets, thus eliminating frequent plumbing bills. Adapted for use in pulp and paper mills, hotels, public buildings and dwelling houses. For ¾ in. to 2½ in. pipe, screwed. For 3 in. to 8 in. pipe flanged.

The Curtis Line of Steam Specialties contains many other notable devices. They are fully described in our No. 50 catalogue. Write for a copy.

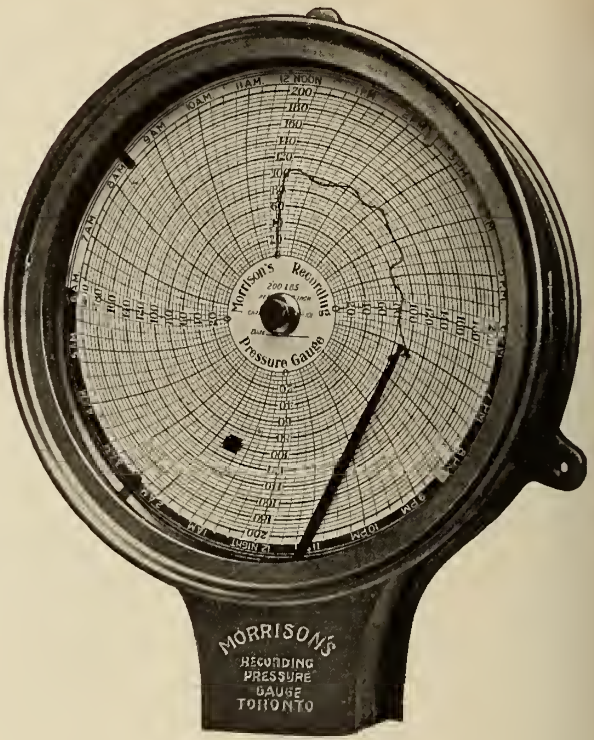
Don't waste your fuel

Morrison
RECORDING
Pressure Gauges



remove the worries of "trying to keep track" from the shoulders of the busy executive.

To the plant superintendent Morrison Recording Pressure Gauges are a simplified form of cost accounting. To the fireman they are a true guide to economical firing. They are indispensable to both.

All steam pressure variations that occur for every hour of the day are indicated with precision on easily read charts. The fireman can tell immediately when more coal is required or other attentions needed. Consequently all waste is cut to the lowest figure.

In choosing Pressure Gauges always specify **"Morrison's"**. There's nearly half a century's experience at your disposal. Write us for further particulars.

Other lines we manufacture are Valves, Injectors, Ejectors, Inspirators, Clocks, Whistles, Bells, Pipe Fittings, Lubricators, etc.

A Jenkins Disc is Quickly Renewed

—without removing valve from line

A Jenkins Disc in a Jenkins Valve is the right combination—a tight-closing valve is assured. The disc has very long life and, when necessary, it can be quickly renewed with the valve left in the line.

The compositions of the various Jenkins Discs are the result of constant study and 58 years' experience in disc manufacture. Each is exactly suited to the particular service for which it is intended.

Use the disc ONLY in the particular service for which it is recommended. If in doubt as to the kind of disc you need, let us know what work it is intended to do, and we will recommend the right one or prepare a special composition to suit your requirements.

Three times the Weight— three times the Strength!

Patented Cold Storage Doors are so-called because of their patented **hardware.** Doors, in themselves, are differentiated by the quality of lumber, quality and quantity of insulation, and care and skill in general construction. The door proper should be of sufficiently heavy material and so securely built as to withstand the grind of time.

But the principal differences in doors are the differences in hardware. The **hinges** should be more than a mere "strap"—as of old. The **fastener** must do what its name implies—continuously—year in and year out.

The hardware on Jamison Doors is practical. The Spring Hinges, for instance, are adjustable—so that a slight turn of a set-screw will keep them 100% efficient—as good as new—by forcing the door tight against its seals of contact. The fasteners are "sure"—they eliminate any possibility of rebound through compression when the door is **slammed.** In fact, the **harder** the slam, the **tighter** it grips.

These patented features are perfect—proven so for 17 years. Probably one reason they stand the gaff so successfully is because of their **weight.** Experience tells that science combined with strength always wins. Which brings us to this: the hardware on Jamison Doors is **three times the weight** of hardware on other doors.

Learn all about Jamison Products. Write for our Catalogue No. 10. You'll find it interesting. Address Desk No. 11.

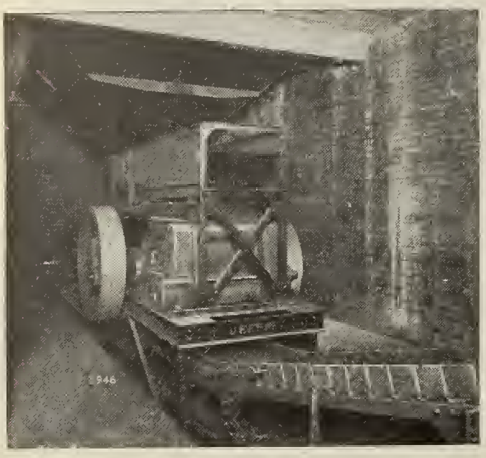
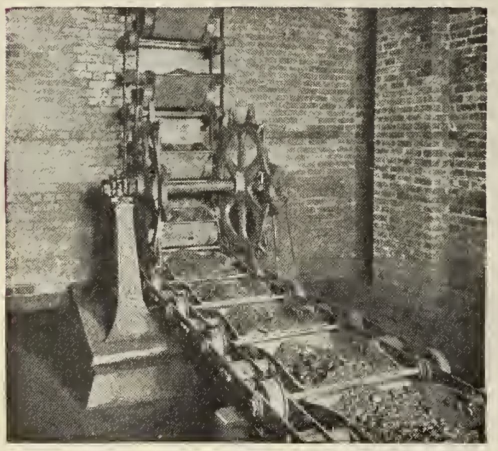
When Your Coal Comes Here's The Way To Handle It



Here is pictorial evidence of how hundreds of large and medium sized power plants are handling their coal expeditiously, mechanically, and at lowest cost.

From Gondola Car to Receiving Hopper—to Reciprocating Plate Feeder—to Single Roll Crusher (which reduces coal to desired stoker size)—to Apron Conveyer—to Pivoted Bucket Carrier—to Bunkers. (The carrier also distributes ashes to bin or railroad cars.)



If the capacity of your plant does not justify the use of a Pivoted Bucket System, there are other types of Jeffrey Coal and Ashes Equipments to fit the requirements and conditions.

Our trained Engineers are at your service to assist in the selection of the equipment you could most profitably install.

BURT OIL FILTER

Dirty oil enters waste oil receptacle and passes through small perforations, flowing thence horizontally to the two filtering cylinders. Heavy impurities fall by gravity into sediment pan and do not clog up filtering cloths. Each cylinder wrapped with cloth through which oil must pass before entering filtering cylinder. Oil passes through animal bone black, and down through the two tubes into bottom of filter. Oil is spread out in thin film by means of plates attached to bottom of tubes, and is thoroughly washed by water. Any remaining impurities in the oil drop to the bottom of the filter and can be flushed out when desired by opening gate valve which connects with sewer.

Oil costs cut 50% by Filtration

1. Oil Filters can be supplied in capacities from 5 gallons per 24 hours up.
2. Capacity can be increased at any time by adding additional units.
3. Filters can be used with or without an oiling system.
4. Guaranteed to clean heavy as well as light oils.
5. The result of many years' experience in building thousands of Oil Filters.
6. Will save 50% of oil consumption as oil can be used many times.

Small Ammonia Compressors

In Class ER-A and FR-A Ammonia Compressors are found features of advanced design and construction. These horizontal, double-acting units represent a step forward in ammonia compressor practice, giving to plants of comparatively small tonnage a modern, reliable and efficient compressor.

The unusually large port and lift openings of Ingersoll-Rand Plate Valves and the unrestricted gas passages in the cylinder, result in the most efficient compression of gas.

Lubrication is entirely automatic, cylinder and stuffing box having separate feeds from force-feed lubricator. Bearings, crosshead pins, connecting rod and crosshead are oiled by the enclosed splash system.

Bypass connections for starting, relief valves, stop valves, and pump-out piping are all bolted to the cylinder casting resulting in a self-contained machine.

Class ER-A Belt Driven Compressors can be furnished complete with short belt drive and electric motor—an arrangement insuring better belt contact and a material saving in floor space. Class FR-A Steam Driven Units have Balanced Piston Steam Valve and Wide Range Automatic Cut-off Fly-Wheel Governor.

Bulletin K-314 contains illustrations and descriptions of both types. Send for a copy now. It will pay you later on.

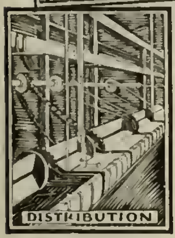
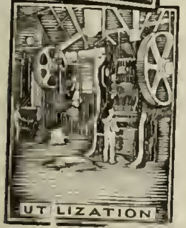
"Steam's Up!"



PREPARATIONS have been made for the greatest show of its kind **in the world!** This is saying a great deal—but it's a fact.

A complete exhibition of the most efficient methods and apparatus for the generation, distribution, control and utilization of power, it will give you definite information of great value in your daily work.

Dec. 3—8, 1923
GRAND CENTRAL PALACE
NEW YORK



The great diversity of exhibits will be a delight to the engineer who likes to "get down to brass tacks." You can turn from one thing to another and see something new every minute.

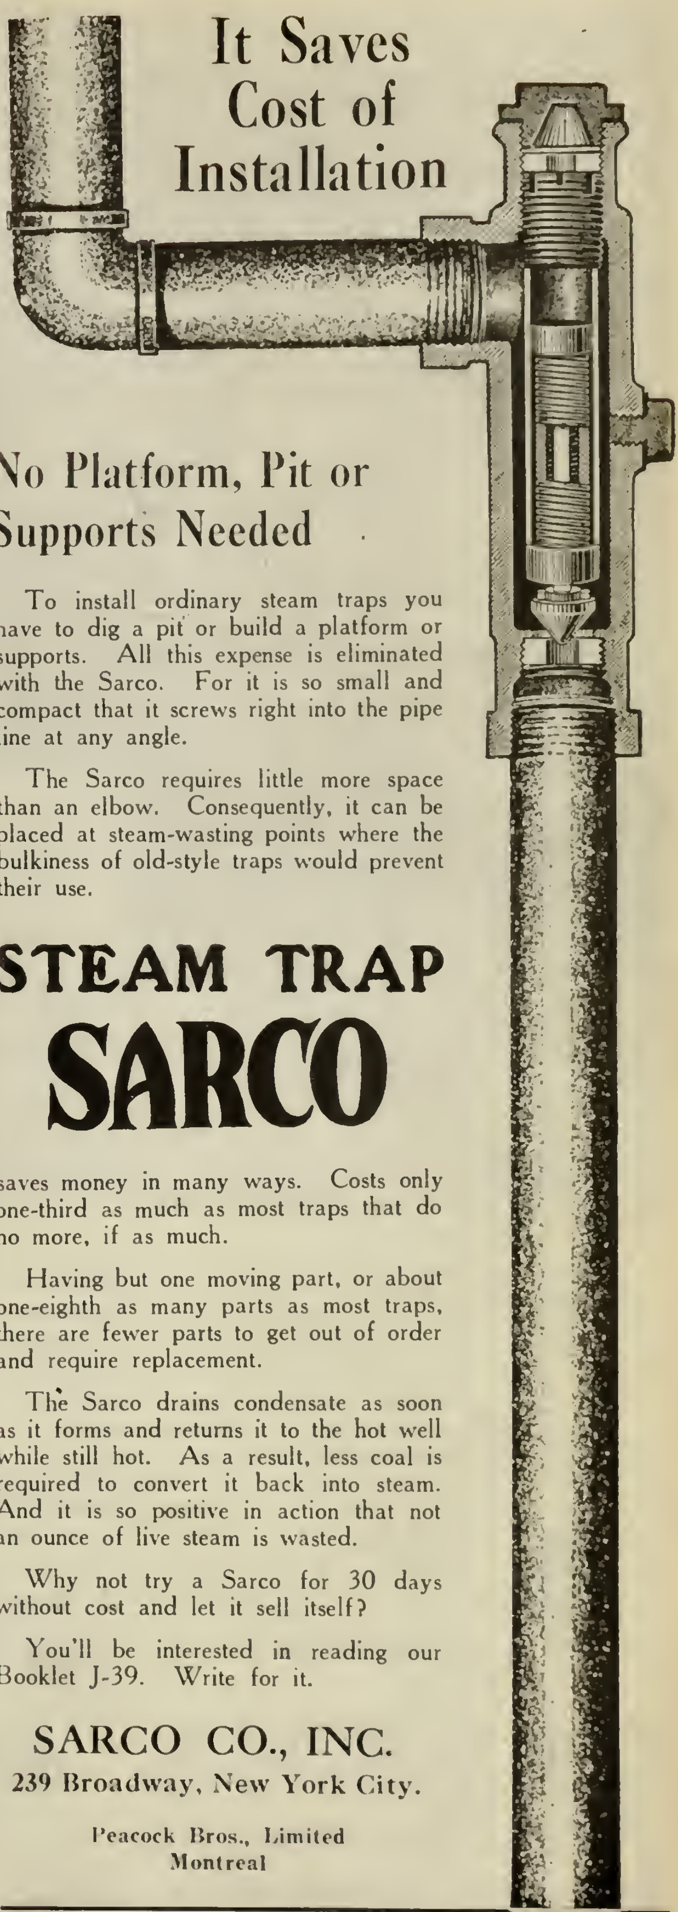
This will be a LIVE show indicative of the importance of Engineering.

Remember the date and come.

To Manufacturers! If you have something of positive merit and capable of comparison which is used either in producing, transmitting or using power or some mechanical equipment, or supply or materials used by the mechanical industry we welcome you as an exhibitor. Every application is subject to Exhibits Committee approval and no article can be exhibited unless it possess real merit.

For further particulars address

NATIONAL EXPOSITION OF POWER
AND MECHANICAL ENGINEERING
Grand Central Palace New York



It Saves Cost of Installation

No Platform, Pit or Supports Needed

To install ordinary steam traps you have to dig a pit or build a platform or supports. All this expense is eliminated with the Sarco. For it is so small and compact that it screws right into the pipe line at any angle.

The Sarco requires little more space than an elbow. Consequently, it can be placed at steam-wasting points where the bulkiness of old-style traps would prevent their use.

STEAM TRAP
SARCO

saves money in many ways. Costs only one-third as much as most traps that do no more, if as much.

Having but one moving part, or about one-eighth as many parts as most traps, there are fewer parts to get out of order and require replacement.

The Sarco drains condensate as soon as it forms and returns it to the hot well while still hot. As a result, less coal is required to convert it back into steam. And it is so positive in action that not an ounce of live steam is wasted.

Why not try a Sarco for 30 days without cost and let it sell itself?

You'll be interested in reading our Booklet J-39. Write for it.

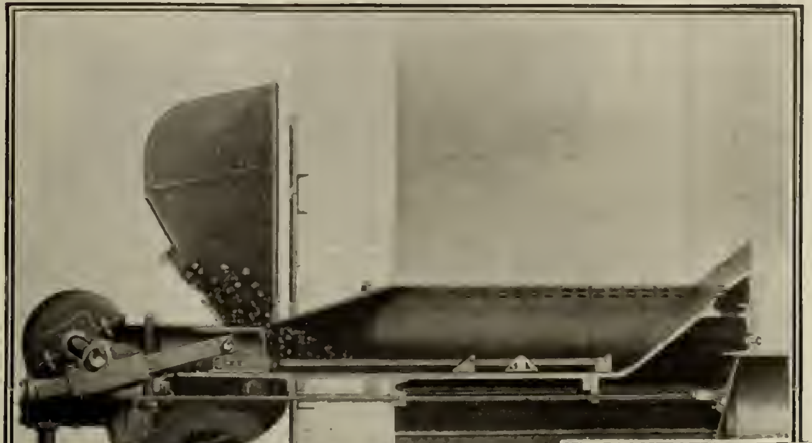
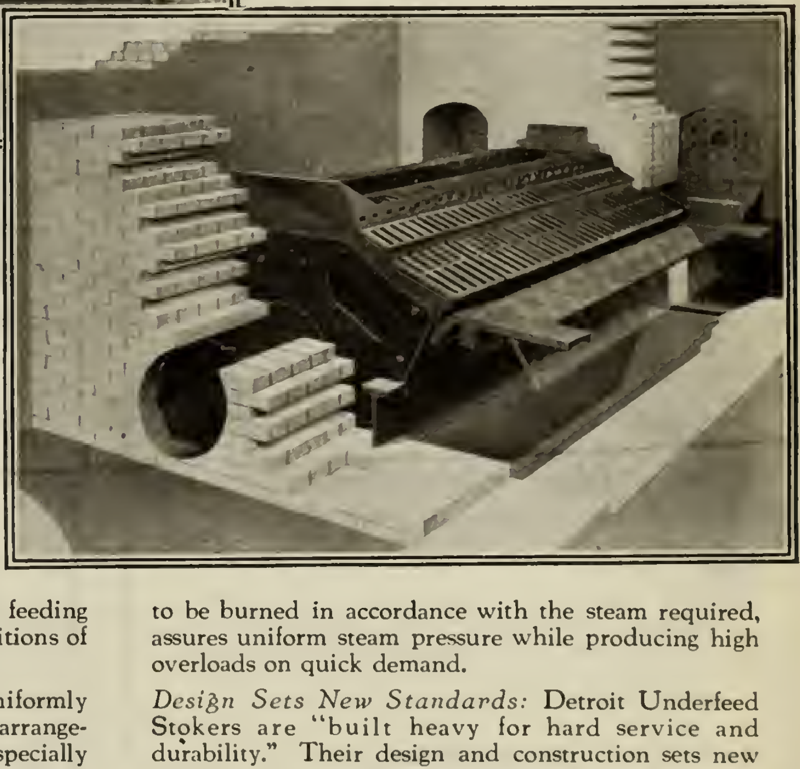
IMPERIAL OIL LIMITED

Design and Construction of Detroit Single Retort Underfeed Stokers



Assure Complete Control of Combustion



Complete Control of the Fire: The Detroit Single Retort Stoker can be operated from the same engine or motor which operates the fan, and distinct regulation is provided, whereby the feed of the fuel to the furnace may be increased or decreased as desired, without changing the speed of the fan or the air pressure. This is accomplished by changing the position of the sliding block on the connecting rod, in or out, while the stoker is running, thereby feeding more or less coal to suit the requirements.

The ram and pusher rod are connected to the crank through the connecting rod or driving bar, which has a simple lost motion device so arranged that the entire travel of the feeding mechanism may be adjusted to suit the conditions of the fire, and the fuel to be burned.

Regulation: Fuel is delivered below the fire uniformly throughout the entire length of the retort. The arrangement for admitting air under control through specially designed tuyeres at both sides of retort, together with the means provided for regulating the amount of coal to be burned in accordance with the steam required, assures uniform steam pressure while producing high overloads on quick demand.

Design Sets New Standards: Detroit Underfeed Stokers are "built heavy for hard service and durability." Their design and construction sets new and higher standards in stoker manufacture. Progress is marked by an ever growing stream of repeat orders.

You will never know what a REAL stoker should and can do until you install a Detroit Underfeed. Ask for Bulletin 228

It's Insulation that does it

A TINY FLAME keeps the Eskimo's igloo warm and comfortable, despite the fact that the outside temperature may be many degrees below zero.

It's insulation that does it. Millions of microscopic air cells formed between the particles of tightly packed snow break up heat penetration and hold it within the hut. Large air spaces are not as effective, as the U.S. Bureau of Standards have decisively proved, and the perfect heat insulation only needs in addition to its countless minute air cells, a composition which withstands high temperatures, and sufficient structural strength.

All these requirements are found in Sil-O-Cel Heat Insulation—in world-wide service on all types of high temperature equipment. Tests by the Bureau of Standards prove it to possess a lower heat conductivity than any other insulation suitable for high temperatures. Furnished in forms which withstand, without shrinkage, direct heats of 2,000° F., Sil-O-Cel has ample structural strength, is easily applied and permanently effective.

A type for application to boilers, furnaces, ovens, kilns and similar heated units without change in design — Brick, C-22, Block, C-3, Powder, and Cements.

A CORRECTION

The crushing strength of SIL-O-CEL Insulating Brick was incorrectly reported in last month's advertisement as being 400 lbs. per square ft. This should read "400 lbs. per square *inch*" or 28 tons per square foot.

Write nearest office for complete information given in Bulletin W-6C, or mail the coupon.

One New Plant After Another

Uses

"Canadian"

Apparatus

THE latest addition to the Essex Station of Public Service Production Corporation will, like the previous section, have Canadian Stoker Fans and Induced Draft Fans making a total of 18 Forced Draft and 12 Induced Draft Fans in this plant.

For each successive installation our engineers studied space conditions, capacity requirements and pressure-volume characteristics, selecting from among our designs the sizes and types to give the best results. This service is at your command not only for power plant equipment but also for fan system heating, ventilating, air conditioning and drying installations, blowers, conveyor fans and forge shops. Write for Catalog to Dept. 12.

Removes Every Drop of Water

LOSSES amounting to thousands of dollars each year, as well as many serious accidents, are caused where condensation is not properly drained from coils, pipe lines, separators or other apparatus.

Steam traps of many designs are used to remove the condensation. To be efficient they must remove all the water and discharge it as fast as it condenses. They too must avoid any discharge of steam pressure. This is exactly what the Fisher Steam Trap is designed to accomplish—and what it is accomplishing in the many plants where it is installed.

If your present trap is not in every detail satisfactory, you will make no mistake in installing a Fisher Trap.

Fisher Features

The Fisher Trap has many superior features. Valve seats can be changed instantly without disturbing pipe connections. Has intermittent discharge, eliminating wire drawing of valve seat. All parts extra heavy. Float made of cast iron, open bucket type, which is trouble proof. Lifts condensation two feet to each one pound pressure on the trap. It has many other features, too, in which you will be interested. Write for complete description.

POWER HOUSE

ARTHUR MURPHY
Editor

CAMPBELL BRADSHAW, Managing Editor

J. MACTAGGART
News Editor

Wants His Men to Advance

WHEN Walter J. Hudson, field engineer of Power House, was in Sault Ste. Marie last week one of the family of readers paid Canada's power plant newspaper a compliment by advising seventeen of his assistants to subscribe. He explained to Mr. Hudson that he did this for the good of his organization.

"All my men are interested in new developments in the power plant field and they certainly can't get better dope anywhere than in Power House, particularly in the past six months."

This chief believes that the more his operators know the better it will be for his boiler room as well as for themselves. And he's chief engineer of the huge Spanish River Pulp and Paper Mill plant.

Continuing the compliments, another man, representing a leading stoker manufacturer, recently said: "What you are now publishing in Power House comes nearer to being 'real meat' for the engineer and manufacturer than anything of the kind we have ever had in the industry. Keep up the good work."

That being the case, every executive, superintendent and engineer in Canada should read Power House, for knowledge is an asset; ignorance a liability. You can't keep on taking out of a barrel unless you keep on putting into it. That is to say, an engineer who stores up his knowledge of power plant operation, must constantly draw from that store. Unless he reads and adds to his knowledge, he will soon find himself scratching the bottom of the barrel.

No man can have too much knowledge of the industry on which he depends for his daily bread. When any of us think we know all there is to know—well, we're getting pretty close to the bottom of the barrel. Some one once said, "Ignorance is bliss." It isn't. It's blisters.

Is It Lack of Incentive?

IT IS universally conceded that the good performances obtained during boiler tests are seldom, if ever, duplicated under average daily operation. Yet, if the conditions of load and service during the test were normal working requirements, it must be admitted there is no other reason for performances falling down, except the failure of the operators to carry the work through in the way in which it was done during the trials.

There may be many reasons for shortcoming — lack of means or knowledge—but it would appear that the most common ones are the neglect of the management to assist the men for a long enough time to make the new practice a sort of second nature to them—a habit—or to provide the men with sufficient incentive.

Proof of the truth of this statement is to be found in a report made to Walter N. Pollakov, one of the world's outstanding specialists on power plant work, on a plant where earlier actual results were very far from being obtained after a short time of operation under changed conditions.

To quote the report: "One hundred and eighty thousand pounds of coal were handled by four men in 24 hours. Two men working together 12 hours each day and passing 45,000 pounds each, could not stand the work; it was too hard. This was because the shovel had a short handle and they had to bend too low; the shovel held only 16 pounds of coal instead of 21.5 pounds, causing the men to bend too many times per ton; the wheelbarrow held only 250 pounds, causing too many trips. When a man was given the right kind of a shovel and a wheelbarrow holding 400 pounds, yet throwing less weight on his arm when lifting the load, he handled 65,000 pounds in eight hours and found his job much easier than before."

In a power plant it must not be forgotten that the men can keep a pretty accurate check upon the amount of coal used to carry a certain load. If, as a result of better work and closer attention on their part, they succeed in saving a few tons of coal they know that this saving is only in a measure due to improved facilities provided by the management, for ultimately a considerable part of the saving results from their willingness and exercise of skill. It is therefore but just that under such conditions they should share to some extent in the savings.

Get-Rich-Quick Schemes

THE greatest get-rich-quick scheme in the world is the distribution of ideas, says James E. Noble, of Toronto, in a letter the other day. And the average reader will agree he's right. "Suppose you have an idea that isn't worth more than ten cents. If you give that idea to—well, say, to ten thousand readers, it's immediately worth a thousand dollars."

Continuing the thought of this reader a little further, let's consider this: Every issue of Power House is crammed full of ideas, each one of which is worth more than ten cents. If you get all of these ideas, and make them your own, you get several dollars' worth a month. And if you pass these ideas along to your firemen, for example, and have them use the ones they can use, you will see other dollars showing up on the right side of the ledger—in reduced coal bills for your employer—in wage increases for yourself.

And another point, while we're at it. Every time you pass a ten cent idea to Power House—or a five dollar idea—that you have used—and it passes the idea to the power plant field, thousands of engineers have been enriched just that much. Send in your ideas, please.

Those Meeting Nights

WHEN two men meet, and each has an idea, and they exchange their ideas, each goes away with two ideas. And that's what happens at association meetings. Meeting nights are nights for the exchange of ideas. The man who misses a meeting of the Canadian Association of Stationary Engineers, of the Universal Craftsmen's Council, or of the Montreal and District Association of Engineers, misses all the ideas of the men who answer "present." The man who brings his troubles to the hall, and lays those troubles at the feet of his fellows, carries home a kit full of joys—of practical information.

Then, too, meeting nights are nights for men to get better acquainted. In days of old competitors kept away from each other. Now they are on friendly terms. They get near each other. How much more can engineers profit by such friendliness and nearness?

Cutting Down Losses by Means of Draft Control

*By ROBERT JUNE, A.S.M.E.

In Maintaining Combustion Efficiency There Are Few Factors More Important Than Draft Regulation—With too Little Draft Huge Operating Losses Occur—With Too Much Draft the Losses Are Just as Costly

FOR each individual furnace there is a variable draft loss, which is affected by a number of factors. The air necessary for combustion must pass through the grate and through the fuel bed. With large openings and short passages such as occur when large uniform lumps of coal are thinly spread on a grate, the draft loss is extremely small.

With fine coal, or coal of variable sizes which packs well, and with deep fuel beds the resistance to the passage of the air is much greater.

Should we attempt to supply the same amount of draft for both fuel beds, we would have with the thin fuel bed and the large lumps a condition where the coal would be rapidly burned on certain sections of the grate, leaving the fire thin at these points, and as a matter of fact, uncovering the grates, so that there would be very large losses due to the excessive amounts of air.

With the thick fuel bed offering considerable resistance to the passage of the draft, due both to its thickness and more compact nature, we should have incomplete combustion, with low CO_2 and high CO, and large volumes of dense smoke pouring from the stack.

Coal Needs Vary

Thus we find that for every kind and grade of coal, for every furnace, and for different rates of combustion in the same furnaces, there is a certain draft from which most economical and satisfactory result are secured.

Fig. 1 gives a good general idea of the draft required to burn a number of the most commonly used steam coals at various rates of combustion. These are not absolute figures but simply indicate common experience.

It will be seen that with the free burning bituminous coals a comparatively light draft is most economical. The amount of draft required increases as the fixed carbon increases and the volatile decreases. The highest drafts are thus commonly required for small sizes of anthracite. It should be understood of course that not only the composition of the coal, but the percentage of ash, has a bearing on the draft required.

To sum up: there is one best draft for each boiler with a given fuel and a given rate of combustion. This best draft can be readily determined by experiment.

Draft Gauges Essential

If you are going to operate at a draft best suited to your fuel and your rate of combustion, you must know when you have secured that draft and whether you are maintaining it. This means that the use of a draft gauge is essential.

This is the fourth in a series of articles by Robert June, the well-known authority on power plant management. The articles deal with the dollars and cents end of power plant operation and maintenance. Succeeding articles deal with such live topics as Safe and Efficient Boiler Operation; Stoker Operation and Maintenance; What Management Should Know About Coal and Ash Handling Equipment; Steam Piping; Efficient Turbine Operation, etc. The series is timely and should prove of value to every Canadian engineer.

Let us suppose that your boilers are equipped with draft gauges. Unless the firemen are making use of the information furnished them, you will be surprised at the variety of drafts which you have in your plant as you go from boiler to boiler. The trouble is this, the firemen know that draft is a good thing and their inclination is to make too good use of it.

It is a universal custom in designing power plants to provide for an excess of draft. Then to throttle this down dampers are furnished. Now the great trouble is if the firemen either leave the damper wide open, or else open entirely too wide for the purpose in hand. This is on the assumption that you do not have automatic damper control, of which more later. The point here is that the draft gauge tells the story and the damper controls it.

Use Ash Pit Door

Suppose you have a hand fired plant, and the firemen do not adjust the dampers to the load. What then is their procedure? The answer is that they use the ash pit door for this purpose, and that this is the most expensive procedure.

Close the ash pit doors and you will note that the vacuum on your draft gauge is greatly increased. The result of this is to speed up the inflow of air at all of the cracks, crevices and holes in the boiler setting. Flue gas temperature is reduced and steam production is checked, but the process is a wasteful one.

The answer is—if nothing better can be done at least see to it that manual damper control from the front of the boiler, so arranged that the fireman can get at it as easily as he does the ash pit doors, is provided. Then compel the fireman to use the dampers in preference to the ash pit doors.

Keep Fireman in Mind

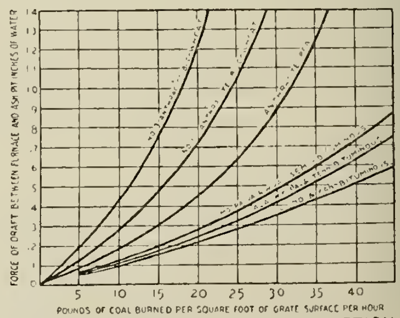
Now getting back to the draft gauge. You are buying this for the fireman, and he is the man to keep in mind. If the gauge tells him what he wants to know and in a way which he can understand and at the moment when he needs the information he will use it—not otherwise. Here are the points to keep in mind:

1. Provide a draft gauge for each boiler furnace.
2. Locate gauges at the most convenient and accessible point. Put them at the front of the boiler at a convenient height so that the fireman does not have to step out of his way a foot to read them.
3. See that the scales are large and easily read. If necessary provide an electric light for the gauge. An unlighted gauge is not much good in a dark boiler room.

Fig. 2 shows a typical draft gauge with a range of 75 hundredths of an inch of water.

Automatic Control

Automatic control as applied to forced draft involves the consideration of three factors: the provision of air supply in-



DRAFT REQUIRED AT DIFFERENT COMBUSTION RATES FOR VARIOUS KINDS OF COAL

Fig. 1.

---

*Specially written for Power House. Copyright 1923, by Robert June.

troduced beneath the fuel bed, the feeding of the fuel, and the draft over the fire.

To govern these factors so that they may be utilized to the best advantage we must control the apparatus which supplies the forced draft under the fire, we must control the rate at which the stoker feeds the fuel, and we must control the damper or it may be the induced draft fan in the boiler breaching, which controls draft over the fire.

Now, first and last, a good many different types of equipment have been developed for the purpose of securing automatic control. Speaking in a general sense this equipment as a class has given effective service and has effected worthwhile economies, which have made it a good investment in the plants where it has been installed.

A straight line is the shortest distance between two points. This being the case, if you want to maintain an even steam pressure, the most effective means of accomplishing this result is to have the steam pressure directly control the forced draft fan. This is the direct straight line and it is a better arrangement than to have the steam pressure directly control the damper and then let the draft over the fire in turn control the forced draft fan.

In following out this principle of reasoning we arrive at once at the proposition that two or more sources of control may perhaps be better than one. Here we run counter to some exponents of a single source of control. Let us examine the situation as impartially as possible.

Control of Forced Draft

Our forced draft fan is operated by an engine or motor, so that we can govern it through the medium of regulation on the steam lines to the engine, or in the electric circuit of the motor. We have the choice also of letting the governing factor be the amount of fuel supplied, the draft over the fire, or the steam pressure. Now, if you want to raise steam pressure in a hurry there is one reliable and immediate method, and that is to increase the draft. Setting about the matter in any other way simply complicates the situation and increases the length of time it takes to produce the desired results. Falling steam pressure is instantly compensated for by an increased draft.

Granted that this form of control is adopted you have to decide on some modification of it when more than one boiler takes air from a fan. The modification sometimes used is that of arranging to govern the butter-fly gates and the air ducts leading to individual boilers, by the rate of combustion in each boiler. This does not work well in practice, since the greater the amount of combustion in an individual boiler, the greater the air supply, and therefore, still greater the increase in combustion. In other words, a condition is created whereby one boiler tends to pull the load away from another.

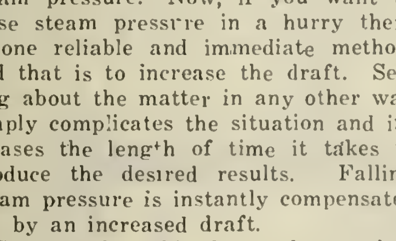


Fig. 2—Draft Gauge.

Therefore, the proper way to handle the butter-fly gates is to determine the best average point at which an equable distribution of the load can be obtained and then to set the butter-fly gates permanently in this position. This method eliminates see-sawing, as each boiler will take its share of the plant load at all times without any tendency toward "hunting."

Draft Over the Fire

The amount of draft over the fire is directly influenced by the damper. Here again, the shortest distance between two points is to have the draft control the damper. The point simply is this: For each given rate of combustion there is a certain draft over the fire which assures the highest economy. An even draft can be maintained most readily by shifting the position of the damper. To let the steam pressure govern the damper is to go considerably out of our way and to have a less satisfactory result than if we regulate the draft over the fire by means of the damper.

To make this still clearer, suppose we open the damper by a change in steam pressure. We then find that the damper must be open an appreciable length of time before the forced draft fan has increased the amount of gases to a volume corresponding to the opening. In the meantime the economy of combustion has been adversely affected. We need to separate very clearly in our mind these two propositions.

Proposition 1.—The maintenance of steady, even steam pressure is of value only in its relation to load conditions. Governing the forced draft fan from the steam pressure is the most direct method of maintaining uniform load requirements. While highly desirable and frequently absolutely necessary it is not primarily a means of effecting economies. The savings may range from 2 to 5 per cent. of fuel.

Proposition 2.—Damper regulation controlled by draft over the fire is one outstanding means of effecting marked economies in combustion. Here the savings in fuel may range from 5 to 15 per cent.

Damper regulation from the draft over the fire is, therefore, recommended for all plants. Where there are a number of boilers in a plant direct control of each damper from the draft over the fire in the boiler to which it is attached is a very much better proposition than to attempt to move all dampers simultaneously without regard to the conditions obtaining in the individual boiler.

With mechanical stokers the feed of fuel to the furnace may be arranged to give constant steam pressure, constant draft over the fire, or it may be made to increase or decrease with the load on the boilers. The latter method is, of course, theoretically the best. If you could vary the amount of coal just as the load varied you would have an ideal condition. Unfortunately combustion equipment manufacturers have not yet, as a class, been able to solve the problem of devising a simple, efficient and dependable control of fuel feed from the steam flow.

For the present we must content ourselves with indirect control of the fuel feed. Here we have our choice of controlling the fuel feed from the draft over the fire or from the steam pressure. Utilizing the draft over the fire for this purpose is not a satisfactory arrangement for a number of reasons. One of them is that the control must be extremely sensitive as to have a variable ranging from 0.05 to 0.15 inches of water to control a stoker, which determines the output of the boiler.

This brings us back then to the control of fuel feed from the steam pressure, or if preferred, from the forced draft fan. Either arrangement is satisfactory and possesses the advantage that increases or decreases in the supply of coal directly corresponding with increases or decreases in the air supply.

Stoker control systems designed along these lines are rendering satisfactory service in literally thousands of plants. There is no reason why they should not be unhesitatingly adopted by any power plant operator.

Points to Remember

Here are points to remember in purchasing boiler room apparatus, particularly controlling devices.

1. The apparatus should be as simple and elementary as possible, telling the boiler room crews exactly what they need to know and no more. All readings should be direct so that calculations are unnecessary.

2. Strength is just as desirable as simplicity. Boiler room apparatus is subject to a good many hazards and unless it can successfully withstand bumps and knocks it is of little value. Moreover, the apparatus must be able to operate accurately when covered with dust and grease.

3. The apparatus should be so designed that it can be installed by the operating engineer in charge of the plant without having to go to the expense of an engineer from the manufacturer's factory.

4. Directions for cleaning and repairing the apparatus should be so clear that the operating engineer can understand them readily and can make the necessary repairs when required.

5. Control apparatus should be sensitive enough to maintain desired combustion conditions without hunting, racing, see-sawing, or lag.

Safety Factors in High Pressure Boiler Design

*By D. S. JACOBUS

In Boilers Built for 1200 lb. Pressures by the Babcock and Wilcox Company, the Superheater is Placed Above a Series of Tubes in a Drop Leg and Below the Main Body of Tubes

JACOB PERKINS was a pioneer in the use of high-pressure steam. In 1822, over one hundred years ago, he made an apparatus in which water was heated under a high pressure in a generator kept full of water by a force pump, and only a very small quantity of the highly heated water was allowed to escape at a time into a tube, where it flashed into steam and passed on to an engine.

His generator of 1824 is described in the following way in a book entitled "History and Progress of the Steam Engine," by Elijah Galloway, published in 1830:—"The boilers, or steam generators as they are called, are in this case very thick cast iron bars, 5 in. square, with circular holes perforated longitudinally through them of 1½ in. diameter, a transverse section of which is exhibited in the figure. They are arranged in three tiers, A, B, D, and are of sufficient length to lie across the furnace, and to pass through the opposite walls, where their extremities are connected together, by a means we shall presently describe, so as to form one continuous vessel.

"By the operation of the forcing pump, water is continually injected into the two upper tiers of generators, so as to keep them always full, and under the pressure of the heavily loaded valve. The lowest tier of generators contain no water, but are kept at a temperature of about 1,000 deg. F. At each stroke of the engine, a certain quantity of water, heated to about 700 deg. or 800 deg. F., is discharged into the valve box C, communicating with the lowest tier, wherein the water flashes into steam. The steam thus formed passes successively through every pipe in the lowermost range, which is exposed to the strongest action of the fire, before it enters, by a short tube, the safety chamber L, for the supply to the engine, to which it is conveyed by the pipe H. At G is a loaded valve to relieve the pressure, should the chamber become overcharged with steam."

A Critical Pressure

Heating the water to 700 deg. or 800 deg. F. would involve operating at the critical pressure of, say, 3,000 lbs. per square inch.

The late Frederick Sargent talked with me on a number of occasions in regard to the form of boilers that might be developed to meet the demand of increasing pressures. This led to the Babcock and Wilcox Company deciding that it would be advantageous to make experiments on a boiler built along entirely different lines from those it was constructing with the idea of determining the possibilities. This resulted in the design and construction of a boiler between seven and eight years ago in which there was a forced circulation and which had no steam and water drum.

The boiler was purposely made of a form in which it was felt there might be certain difficulties in order to search out the principles involved in such boilers.

The arrangement of the boiler in the form in which most of the tests were made is shown in Fig. 1. In the first tests the water was fed into the cross box most remote from the fire, passed in series through the loops from one cross box to the next, and finally left in a superheated state from the last cross box. But few tests were made on this form, and the boiler was changed by placing the separating tank, dotted in Fig. 1, between the economizer and boiler part and the set of loops nearest the fire which formed the superheater. The boiler was fed in the same way as in the first form, and the steam generated, together with some contained water, passed into the separator. The loops were constructed of 2-in. tubes, and the straight portions of the loops were fitted with cores.

Regulate Water Supply

The water was maintained at a given height in the separating tank by regulating the rate of supply of the feed water, and at the same time a small amount of water was continually bled from the separating tank and returned to the feed water. This insured the passage of a certain amount of water at all times through the economizer and boiler element. From the separating tank the steam was passed to the superheater located next to the fire. The name "Series Boiler" was applied to the apparatus.

It was first intended to place boiler surface ahead of the superheater so that the hot gases from the furnace could pass first over the boiler surface, then over the superheater, and thence over the boiler and economizer surface. In order to simplify the apparatus, the boiler surface was not placed ahead of the superheating surface, and doors were provided in the setting for tempering the gases from the oil-fired furnace to a point where they would be at a low enough temperature to avoid burning the superheater.

After the cores had been adjusted to the size finally used, it was found unnecessary to admit air to prevent the superheater from being burned out even though the oil furnace was at a high temperature.

The superheater tubes became coated with black oxide on the outside, but they did not burn out nor was there any trouble through leakage throughout the tests, although the superheater might have failed eventually had the boiler been run for a longer time. The boiler was operated at a maximum capacity of about 425 per cent. of rating, based on the entire amount of heating surface of the economizer, boiler and superheater. The surface was not arranged in a way to give efficient results, the object of the tests being to determine the features of circulation and the prac-

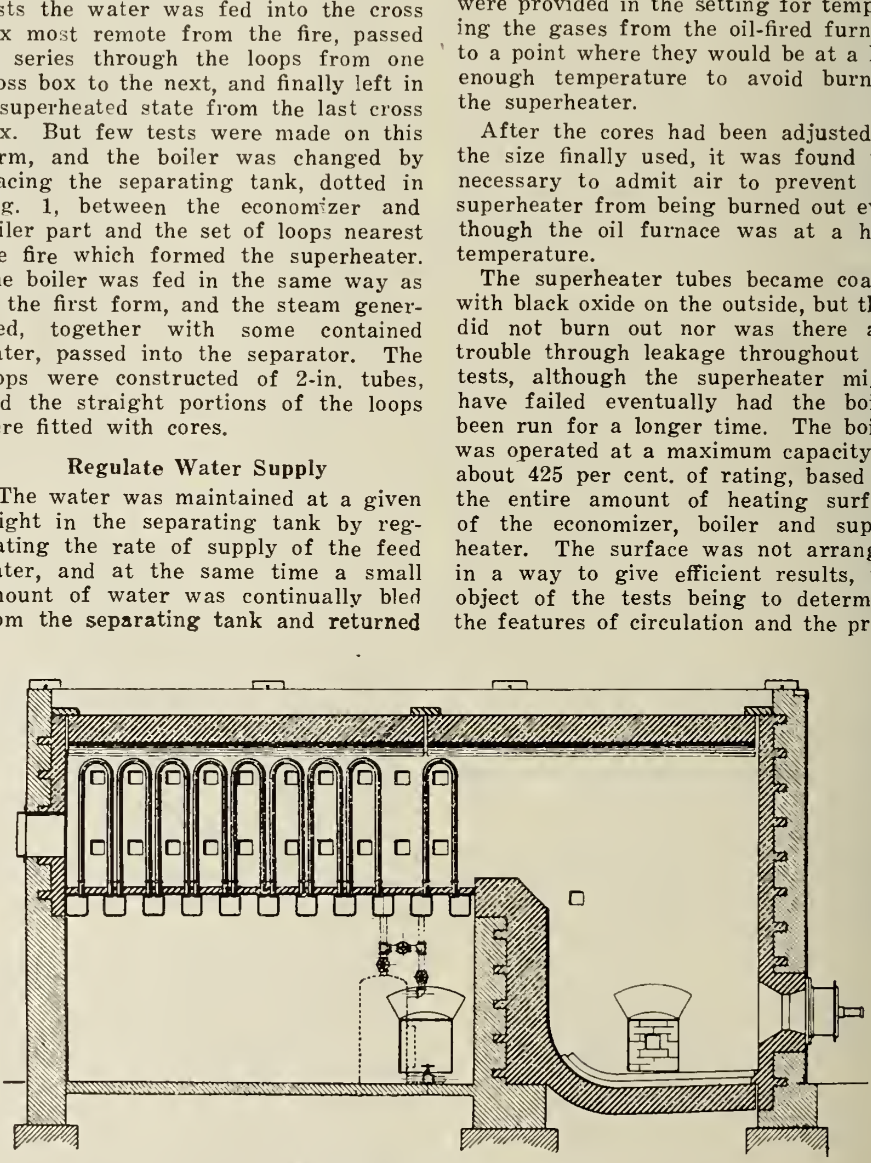

Fig. 1—Experimental Series Boiler.

---

*Advisory Engineer, the Babcock & Wilcox Company.

ticability of operating a boiler of the sort.

In operating a series boiler, care must be taken in starting up to maintain a circulation of water or steam through the boiler. This would necessitate the installation of special arrangements in a power plant, especially if the heat imparted to the boiler in the starting up is returned to the system. Again, it is difficult to operate a boiler of the sort under fluctuating loads, and in any event the feed-water pumping system must have 100 per cent. reliability.

It was therefore decided to build a series boiler to be used in combination with a relatively small boiler, having a steam and water drum. The combined unit shown in Fig. 2 was therefore constructed.

Comparatively Small Unit

This consisted of a boiler with 2 in. tubes having a steam and water drum and a combined boiler and economizer with 1 in. tubes, in which the heating surface was 3.7 times the heating surface of the boiler having the steam and water drum. The unit was a comparatively small one, having 187 square feet of tube surface of the boiler with the steam and water drum exposed to the hot gases, 51 square feet of superheater surface, and 685 square feet of boiler and economizer surface in the section made of 1 in. tubes, or 923 square feet of heating surface in all.

The boiler was fired with oil fuel with a mechanical atomizing burner and operating at 600 lb. gauge pressure. A connection fitted with a valve was run from the steam and water drum to the lowermost part of the series boiler, and this connection was left open in starting up the boiler, so as to provide a local circulation. The unit was run at times at over 500 per cent. of rating, based on the total boiler and economizer surface, and all parts were found to operate in an entirely satisfactory way.

The percentage of rating at which the boiler with 2 in. tubes having the steam and water drum was operated in the high-capacity tests was about 1,500 per cent.

We are building boilers for 1,200 lb. working pressure with wrought steel economizers for power plant surface of the general form shown in Fig. 3, which is illustrative only as certain features of the tube arrangement may be changed. In developing this boiler, we had before us the results secured for the use of 1 in. tubes in a great number of our White-Forster marine boilers for destroyer service and the results of the experiments with the series boiler. A great number of different arrangements were laid out and considered, and the one finally adopted was that shown in Fig. 3, which approaches very closely to a standard Babcock and Wilcox boiler.

Tubes 2 in. in Diameter

In this boiler the steam generating tubes are 2 in. in diameter, which is a convenient size for internal cleaning, whereas it is difficult, if not impossible, to properly clean tubes, say, 1 in. diameter and smaller. The steam and water drum, which is 48 in. internal diameter of forged seamless steel construction, provides a reserve water capacity, making it easy to operate the boiler under all sets of conditions, such as in starting up and under variable loads, and making it unnecessary to provide pumps having 100 per cent. reliability, such as would be necessary for a series boiler.

The tubes are arranged so that they can be thoroughly cleaned on the outside from between the diagonal lanes. The feed water from the economizer passes directly into the boiler, which makes it necessary to build the economizer for a somewhat higher pressure than the boiler. The economizer is made up of 2 in. seamless steel tubes expanded into forged steel boxes.

The boxes are spaced apart to allow the removal and replacement of the economizer tubes from between the boxes with the tubes at an angle which allows the tubes to be removed and replaced with a relatively narrow aisle width. The ends of the horizontal circulating tubes of the boiler are bent so that they enter the drum in circumferential lines which are twice as far apart as the distance between the horizontal circulating tubes where they enter the headers. This greatly increases the efficiency of the ligaments between the tube holes.

There are two circulating tubes runing from the top of each uptake header to the steam and water drum. The boilers are built to meet the requirements of the A.S.M.E. boiler code. Certain features of the forged steel drum are not covered in the A.S.M.E. code, but the general character of the steel in the drum will conform closely to that specified in the A.S.M.E. code for boiler plate and the maximum allowable stress is taken at 11,000 lb. per square inch, thereby corresponding to the figure specified in the code.

Individual Turbines

The boilers built for 1,200 lb. working pressure will be supplied with individual steam turbines. It is the idea to eventually generate all of the steam for a power plant with high-pressure units of the sort, and after passing the steam through several of the high-pressure steam turbines to pass the exhaust steam from these high-pressure steam turbines to a main steam turbine. The steam supplied to the high-pressure steam turbines is superheated to a total temperature of, say 727 deg. Fahr., by primary superheaters.

The exhaust steam from each individual high-pressure steam turbine is returned to a secondary superheater placed with the high-pressure boiler setting at a pressure of, say, 300 lb. above the atmosphere, and is re-superheated to a temperature of, say 725 deg. Fahr., and supplied to the main steam turbine. The individual high-pressure steam turbines therefore serve to reduce the pressure of the steam from the initial pressure of 1,200 lb. to that used at the main steam turbine.

With an economical main steam turbine operated with the exhaust steam from the high-pressure steam turbines, the amount of power generated by the high-pressure steam turbines would be 20 to 25 per cent. of that generated by the main steam turbine. Should the main steam turbine be run at a lower pressure than 300 lb. and at a lower temperature than 725 deg. Fahr., the gain through using the high pressure would be increased and might reach, say, 30 per cent. or more. There is a possibility, therefore, of re-vamping present power stations and considerably increasing their efficiency through using the high-pressure units with individual steam turbines and exhausting the steam into the present steam mains.

In order to warrant the additional investment necessary for installing the high-pressure boilers in an old plant,

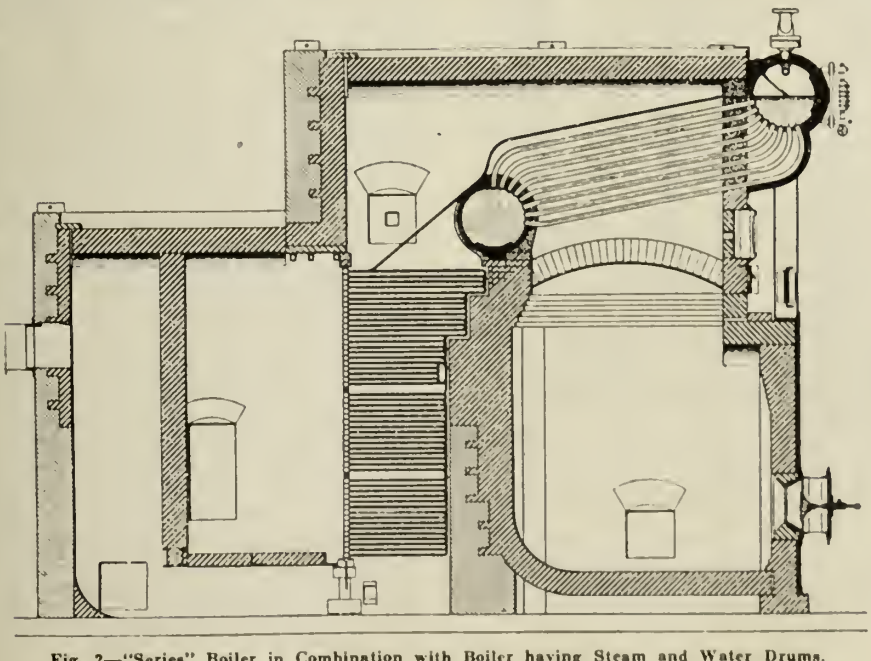

Fig. 2—"Series" Boiler in Combination with Boiler having Steam and Water Drums.

it would be necessary to have a very steady load, or what is known as a "base load condition." The investment would not be warranted under present conditions for a widely fluctuating load.

In place of using individual high-pressure steam turbines for each boiler, the high-pressure steam from a number of boilers could be used for larger high-pressure turbines. Experience alone can demonstrate which system will be best, and no one can say what plan will be adopted in the future in the effort to secure higher and higher efficiencies. There will no doubt be difficulties that cannot be foreseen to be worked out, and those who are pioneers in installing high-pressure units of the sort should be commended for their willingness to spend the time and money that will be necessary in the development.

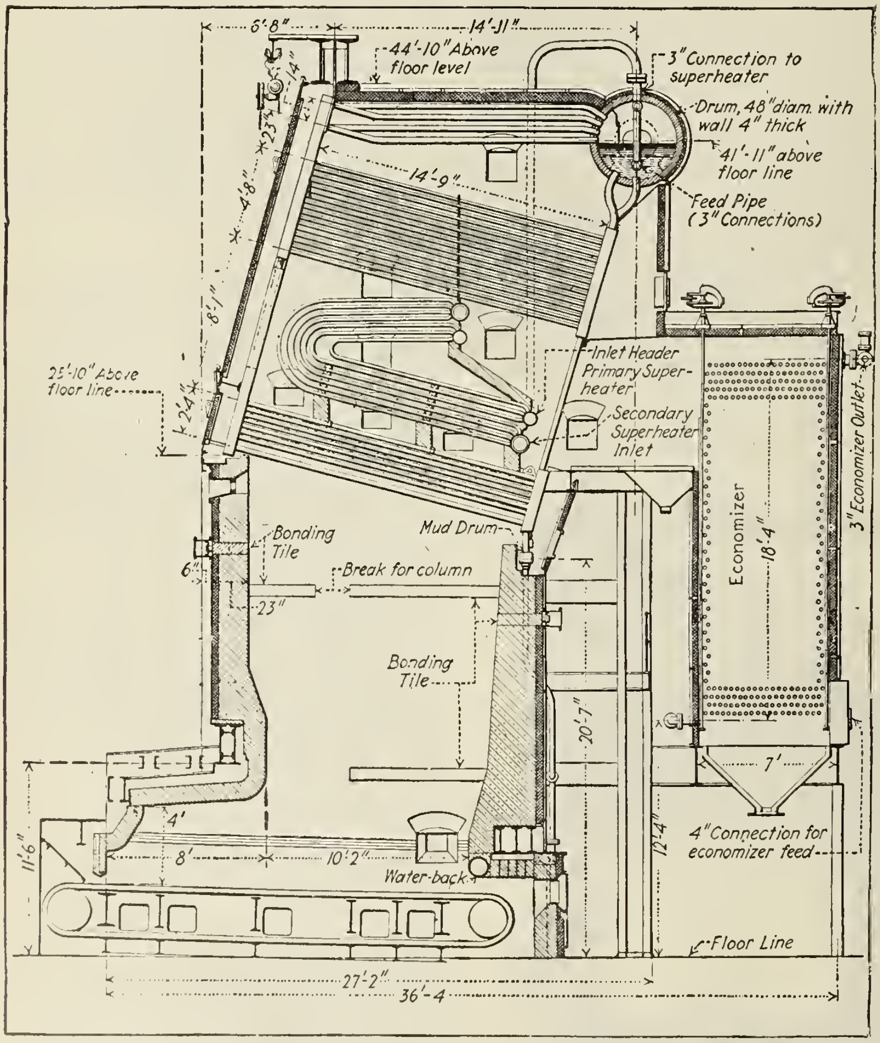
Would Simplify Problem

If it were possible to maintain absolutely tight surface condensers, it would be unnecessary to clean the interior of the boiler tubes, and the problem of designing high-pressure boilers for power plant service would be greatly simplified.

Under present conditions, there is always a chance of leakage at the condensers, either at the tube ends or through the cracking or corrosion of the tubes, and this necessitates arranging the boiler so that it can be cleaned on the inside. Tight condensers and the use of a closed system would also overcome any trouble through corrosion due to oxygen in the feed water on the interior of the economizers and boilers. The fact remains, however, that leakage in condensers has not as yet been overcome, and the problem of both cleaning the interior of the tubes and of removing any excess oxygen from the feed water must be faced in all cases.

The effect of temperature on the lowering of the elastic limit of steel has been referred to by engineers as something that might give trouble in a high-pressure steam boiler. At a temperature of about 750 deg. Fahr. the elastic limit may drop to half that obtained at ordinary room temperatures, and it is important that the effect of this falling off be understood.

The temperature of the saturated steam corresponding to 1,200 lb. pressure is somewhat less than 570 deg. Fahr., and at this temperature the strength of the steel is higher than at ordinary room temperatures and the elastic limit is about the same or only slightly lower, so there need be no apprehension with respect to the boiler proper. The only part that is affected through being brought to a temperature that would cause any material difference in the strength or the elastic limit of the steel is the superheater. Of all parts of a boiler the superheater is the safest as far as its liability to injure anyone or to cause property damage is concerned, as the worst that might happen in case the superheater became overheated would be to burn out or blow out some of the tubes, and this would not ordinarily result in any damage other than to the superheater itself.



SECTION THROUGH BOILER, SHOWING SECONDARY SUPERHEATER AND FOUR-INCH THICK DRUM

Tests Strength of Steel

The effect of a rising temperature is first to increase the tensile strength of steel from, say, 10 to 20 per cent., and afterwards to decrease it, and at 700 deg. Fahr. the tensile strength is about the same as at ordinary room temperatures. At 750 deg. the tensile strength falls off, say, 10 per cent. below what it is at ordinary temperature, and the elastic limit is about one-half what it is at ordinary room temperatures.

In a complicated structure used under pressure at 750 deg. Fahr., the falling off in the elastic limit would result in a liability for leakage, and in such a structure it might be well to use a factor of more than 5 based on the tensile strength. In a structure like a superheater, however, there would seem to be no necessity of providing a factor of safety of more than 5 based on the tensile strength.

We have become so accustomed to the use of relatively high factors of safety in boiler construction to those used in some other lines that we are apt to overdo matters to make sure we are on the safe side. When one considers the relatively low factors used in the design of large guns and for torpedo tubes carrying very high pressures, one feels a great deal safer when it comes to boiler design. Again, in the work we have done in designing and building oil stills and tanks for use at high pressures and at temperatures of 825 deg. Fahr., we made a careful study of the falling off of strength and elastic limit and of the practice in still design that has been found to give safe results, and all this makes us more confident in feeling that the factors of safety we are using in boiler and superheater design are ample.

As superheated steam of higher and higher temperatures is being used in power plants, the time is approaching when it may be necessary to provide some automatic means for preventing the temperature exceeding a certain figure. It has been the general practice to run at a temperature which can be exceeded for a time without giving trouble.

The Babcock and Wilcox Company made experiments over ten years ago to develop an apparatus for attemperating superheated steam and maintaining the temperature at a given figure, provided the initial temperature of the

Motor Trouble in Power Plants and Its Cure

By R. L. TULLIS

Good Commutation the Keynote to Successful Operation of Direct Current Motors—Neglect, Improper Installation or Continuous Overloading Usually to Blame for A. C. Troubles

IT IS the writer's desire to set forth in as clear, concise, and non-technical manner as possible his practical experiences on the care and maintenance of motors.

A large percentage of all direct-current motor troubles can be directly or indirectly traced to the commutator. Good commutation is the key-note to successful operation of direct-current motors. Therefore a few pointers on the proper care of commutators may be in order.

The commutator should be kept clean, dry, and free from oil, grit, smut, etc. If oil or grease is allowed to collect on the surface of the commutator, it will prove an aid to the collection of grit, copper dust, and smut which will soon destroy the commutator surface and cause the brushes to wear away quickly. Again, more serious trouble may be caused by the accumulation of copper or carbon dust in the grooves between the segments of the commutator; a short-circuit will result, and the armature is liable to burn out.

Cut Grease Loose

The commutator can be cleaned and polished while in motion by holding a pad of clean canvas against the revolving surface. Where the commutator is badly oil-soaked or greasy it is sometimes advisable to use a small amount of gasoline to cut the smut and grease loose.

Formerly it was the practice of many operating engineers to apply a small amount of vaseline or a tallow candle to the surface of a commutator. This was supposed to prevent sparking or chattering of the brushes. At best the effect of such treatment is only temporary, and encourages the collection of destructive substances on the surface of the commutator.

Modern engineering practice does not advise the use of lubrication on a commutator. If the surface is smooth and polished and the proper quality of brushes used, lubrication is unnecessary.

Chattering of Brushes

High mica or mica extending above the surface of the commutator is often the cause of sparking, chattering, or jumping of the brushes. High mica is usually caused by the brushes wearing the copper surface more quickly than that of the mica between the segments.

On the other hand, too deep undercutting of the mica encourages the collection of copper or carbon dust worn from the commutator surface and the brushes. This collects in the grooves between the segments, and a short-circuit is liable to result. The depth of the undercutting should vary between 1-32 in. and 1-16 in., depending upon the size of the commutator. The undercutting grooves should be V-shaped or with bevelled edges to prevent cutting of the brushes against the sharp edges. Also the V-shape facilitates the throwing out of undesirable foreign substances by the centrifugal action of the revolving commutator.

Heating of Commutator

Heating of the commutator may be due to a number of causes. Severe overloading will cause sparking and excessive heating of both the motor and commutator. Many motors are burned out by overloading without the engineer becoming aware of the real cause of the trouble. Every engineer in charge of a number of motors should have a portable ammeter which he can temporarily connect in on the line and ascertain whether the motor is pulling more than its rated capacity.

Excessive heating of the commutator may also be caused by poor contact of the brushes. Again, it may be due to burned or roughened surfaces or the presence of dirt, smut, or oil, which prevents proper transfer of current from the brushes to the commutator.

Commutator trouble is often caused by the mica insulation between the segments becoming oil-soaked, which in turn will cause disintegration and honeycombing of the insulation, eventually leading to a short-circuit between the segments or to the shaft of the machine.

Need of Cleanliness

The bearings may become worn and leak or throw oil, which will be drawn into the machine, due to air currents used in the ventilation of modern machines.

As a result of poor ventilation methods many motors and generators suck in and collect a great amount of dust, grit, smut, or lint from the surrounding atmosphere. Therefore, it is advisable to use some type of enclosed or dustproof machine, where the atmosphere is heavily laden with destructive substances.

Moisture, acid, and oil-laden air is injurious to motor insulation; precautions should be taken to protect the motors as much as possible from such conditions.

Occasionally, it is advisable to cover the motors with some form of thin sheet-iron housing; but an the other hand, if enclosed too tight, lack of proper ventilation is liable to cause serious overheating. All motors should be thoroughly cleaned at least once a week by blowing out with compressed air. If oil, dirt, and smut cannot be removed with compressed air, they should be wiped out with a cloth saturated in gasoline.

Portable Blowing Outfit

Very often in large industrial plants there is no compressed-air line near the motors to which a hose and nozzle can be attached to blow out the motors and electrical equipment. In such cases it is advisable to construct a small portable blowing outfit mounted on a four-wheel truck. Such an outfit consists of a small air-cooled motor-driven air compressor (which can be attached to any lighting circuit), together with a pressure tank and any length of small air hose desired. Such an outfit can be wheeled around with each, making it possible to reach motors in inaccessible positions where there is no compressed-air supply line.

A badly grooved and scored commutator is caused by improper staggering of the brushes—that is, they are allowed to follow in each other's track. The brushes should be adjusted or staggered as to completely cover the commutator surface, leaving no uneven surface or high ridges between.

Care of Brushes

If the commutator is eccentric or out of round, badly grooved, scored, or cut, it should be taken out and turned down. However, before putting it back in operation the surface should be polished with fine sandpaper, as the cutting tool used in turning often leaves minute sharp edges or particles, which will cause unnecessary wear on the brushes.

If the commutator is eccentric or out of round, and is not too badly grooved, scored, or rough, it may be trued up or smoothed by the use of a revolving wheel grinder made especially for truing commutators, or it may be stoned by holding a grindstone or medium-grade scythe stone against the revolving surface. The surface should be ground down evenly by working the stone from one end to the other.

The job should be finished with the finest grade of quartz sandpaper and polished with a pad of clean canvas.

Many engineers apply sandpaper while the brushes are down and the motor in operation. This is undoubtedly the easiest, but at the same time an improper method, as fine particles of sand and copper dust are certain to work under and become embedded in the contact surface of the brush. This will cause undue wear and cutting of the surface of the brush and commutator, together with sparking. In a short time the conditions will be as bad as they were before the treatment.

Do Work Properly

In order to do the work properly it is necessary to revolve the commutator with the brushes raised, by some means other than its own motive power.

At the present time, carbon and graphite, or a combination of the two substances, are the main materials used in brush construction. The brushes are manufactured in various qualities and degrees of hardness to suit individual requirements.

Carbon and graphite brushes have come into universal use because they are comparatively soft, less injurious to commutator surface, are superior conductors of electrical current, and can be radially applied without injury to the commutator, making it possible to reverse the direction of rotation of the motor without changing the position of the brushes and without injury to same.

In operating direct-current motors it is important to keep the brush pressure at the proper value. All brush-holders are equipped with adjustable springs, whereby the brush pressure may be increased as the brushes wear down. Insufficient brush pressure will cause sparking and jumping of the brushes.

Hit and Miss Principle

If the brushes wear to any great extent and the brush pressure is not increased, the brushes will fail to make proper contact with the commutator surface. Arcing will take place, the commutator will become burned, and the motor will operate on the hit-and-miss principle, due to the jumping of the brushes.

If the motor is operated in parallel with the lighting system this will cause fluctuation of the line voltage and may cause flickering of the lights on the circuit. On the other hand, too much brush pressure will cause an undue amount of friction and consequent heating of the commutator, together with rapid wear of the brush surface.

Brushes sticking in their holders will cause sparking and troubles similar to those described above. The brushes should move freely and smoothly in their holders without being loose.

If the brushes are loose in their holders and the commutator is rough it will cause noise and chattering while in operation. A set of brushes under proper conditions should last from two to three years. There are exceptional cases where they have been in operation from ten to twelve years; however, under adverse conditions they may only last for a few weeks.

Burning of Brushes

Glowing or burning of the brushes may be caused by overloading of the machine, improper contact, improper fitting of the brushes, or insufficient brush pressure. All brushes should be carefully fitted to the curvature of the commutator. It is not advisable to use graphite brushes where the motors are exposed to oil vapors. Under such conditions dry carbon brushes should be used.

The brushes must be equally spaced about the circle of the commutator—that is, the distance between each set of brushes must be exactly the same, otherwise unbalancing of the armature circuit will result.

The distance between each brush-holder and the surface of the commutator should be identical. If the brush-holder becomes loose, the spring pressure will force it backward, away from the commutator. The position of the brushes will be changed, the brush pressure lessened, and sparking will result.

Pig Tail Necessary

Many engineers make the mistake of installing brushes on motors without pig-tails. The pig-tail is necessary to conduct the current from the holder to the brush, whence it travels through the brush to the armature circuit. Occasionally the pig-tails become loose or burnt off.

Brushes without pig-tails make a faulty, loose connection. If the brushes become loose in their holders, the current will arc between the two; brushes and holders will be pitted and burnt by the action of the current.

A.C. Motor Trouble

On alternating-current motors the commutator, brushes, and brush-holders are eliminated; due to the elimination of these three parts a great deal of the repair and maintenance troubles peculiar to the direct-current machine is automatically done away with.

Probably 90 per cent. of all direct-current motor trouble can be directly or indirectly traced to some form of commutator or brush trouble. Due to the fact that the alternating-current induction-type of motor is void of these troublesome parts, it is probably the most satisfactory prime mover of the present day.

Most motor troubles can be attributed to lack of proper care or attention, improper installation, or continuous overloading above their rated capacity.

Cleanliness is of the greatest importance around all types of electrical machinery; still many engineers fail to realize this fact.

There are hundreds of small installations where the motors are expected to run from year to year without ever being properly cleaned; still the operators wonder why it is that the machines burn out their windings occasionally.

Ventilation Important

Ventilation methods used in the construction of all modern types of machines cause them to suck in and collect a great amount of dust, grit, lint, and other destructive impurities in the atmosphere. Then if the bearings become loose or worn, they will leak or throw oil, which also will be drawn in by the

Demands Revision of Boiler Law

Power House Takes Part in Deliberations at Spadina Crescent on Invitation of Ontario's Minister of Labor

THE wheels of the gods grind slowly—at Spadina Crescent, Toronto. Three pages of the June 5 issue of Power House were devoted to the charge that former Minister of Labor Walter Rollo was "too busy to heed the claim of members of the Canadian Association of Stationary Engineers, of Councils of the Universal Craftsmen, of the International Union of Steam and Operating Engineers, of boiler manufacturers and city officials that "holes" in the Ontario Inspection Act made it the poorest in the Dominion.

And now on the eve of the publication of this issue of Power House, more than four months after the criticism in question had been commented on favorably by daily newspapers throughout the province, a "meeting of representatives interested in the manufacture, repair, sale, purchase, operation and insurance of Steam Boilers and Pressure Vessels has been arranged by the Department of Labor, and approved by the Hon. Dr. Forbes Godfrey, Minister of Public Health and Labor.

In inviting Power House to take part in the deliberations, James H. H. Ballantyne, deputy minister of labor, says: "It is the intention of this department to find out and how far and to what extent the present statutes are effective in meeting and dealing with the most important phases of the Steam Boiler and Pressure Vessel industry, and your co-operation and aid in discussing this important matter will be greatly appreciated."

Let us hope that this investigation will not be farcical—that as a result of the accession of Dr. Godfrey to the portfolio of minister of labor, more will come of it than "the careful consideration of the department." If Dr. Godfrey has any doubt of the absurdity of present conditions, of the absurdity of sixteen inspectors responsible for the proper observance of the Factory Shop and Office Building Act, including four women, being responsible for the inspection of operating boilers, let it be remembered that explosions in Ontario are more numerous than in any other province of the Dominion, despite the fact that the modern steam boiler as manufactured in Ontario, if periodically inspected in a capable manner during operation, is perfectly safe.

suction of the machine. Thus a mixture of oil, dirt, and lint will collect between the adjacent coils and windings; a short-circuit is liable to result, or at least the insulation will be damaged by the accumulation of such impurities.

All motors should be frequently blown out with compressed air. The air pressure generated by a hand bellows is usually not sufficient to thoroughly clean a motor.

All oil, moisture, or acid-laden vapors should be kept out of the winding of the machines. If the bearings throw oil they should be protected by suitably constructed guards. Very often this trouble is caused by worn bearings and can be remedied by the installation of new bearings.

Inspect Bearings Weekly

If the bearings become badly worn they will often throw all the oil out of the reservoir within a few days; while if they are in perfect shape they will retain oil for a long period. To avoid trouble from running dry and burning out, the bearings on all motors should be inspected once per week.

The writer was once employed in a large factory which contained about 200 motors of various sizes ranging from 2 h.p. to 12 h.p. The motors were all of the induction type operating on 220-volt, three-phase, 60-cycle alternating-current system.

In this plant a great deal of trouble was being experienced due to the motors burning out. Nearly every week one or two motors were being sent to the shops for rewinding and repairs; consequently the bills for repairs were large.

A study of the situation soon disclosed the cause of the trouble. Every motor in the building was equipped with the ordinary type of three-pole knife switch for starting and stopping. Nearly every one of the motors was heavily over-fused, and was handled by anyone who had occasion to use them. Many of the motors were heavily overloaded, and when in operation would blow a fuse on one phase of the line.

Due to Bad Bearings

The motor would then continue to run on one phase until it burned out or became badly over-heated. On a number of occasions the motor burn-outs were due partly to bad bearings. If the motor bearings were badly worn and would lose their oil, they would run hot and seize the shaft. Then, when the motor had stopped, the current would continue to flow through the winding until it was burned out.

Ninety per cent. of the motor trouble and consequent expense of repairs in this plant was eliminated by the proper care of motors and in the installation on each motor of a modern type of automatic protective switch, which prevented the continuous overloading and single-phase operation of the polyphase motors.

The air space or clearance between the rotor and fields of an induction motor is very small; consequently, if the bearings wear to any extent, the rotor will rub on the field windings and excessive friction will result. Such a condition should be remedied at once.

Low voltage will cause trouble with the induction type of motors, as the turning power or torque is proportional to the square of the applied voltage; thus half voltage would produce quarter torque, and the motor would become seriously overloaded.

Most motor-bearing troubles can be attributed to excessive belt tension, dirt in the oil, oil-rings not turning, or improper line-up of motor to its load. Unbalanced voltage or a three-phase system will cause motor trouble due to low voltage. If the voltage differs on the two legs of the circuit by 20 per cent., the output of the motor will be reduced 25 per cent., and serious overloading and burning-out of the motors are liable to result.

The writer recently came into contact with a case of an unbalanced circuit in a large plant which contained a great number of small motors.

The current was supplied through step-down transformers. The power and light circuits were taken off the same main line, the motors operating on 220-volt three-phase, 60-cycle current, while the light circuit was stepped down to 110-volt.

Additional motors and lighting circuits were being installed frequently, and the circuit was not equipped with any form of balancer coil; consequently the circuit became badly unbalanced. Both the motors and lights soon began to give a great deal of trouble.

A number of motors were burned out, undoubtedly due to low voltage and consequent overloading, while on the other side of the line the lights would burn out in a short time. The trouble caused

"Jokers" Weaken Ontario Act

Engineers Feel Examinations Should be Standardized and Not Designed to Offset Variations in Labor Market

WHO is responsible for the present administration of the Ontario Stationary and Hoisting Engineers' Act? As pointed out previously in Power House the manner in which this act is administered at present, tends, in contrast with a province like Quebec, to place Ontario in the position of not knowing exactly what qualifications are required for the issuance of certificates, and raises doubt as to whether the demand for these qualifications is constant and consistent.

The regulations promulgated by order in council with regard to the enforcement of the act would appear to be partly responsible for the inconsistencies and irregularities in the act's administration. On the other hand, they certainly are not responsible for the variation in the standard of the examination set from year to year such as has apparently been the case in past years.

It has been suggested on several occasions that this variation in the standard of examination was designed to offset variations in the labor market, the examinations being more severe in the days of labor plenitude and less of an obstacle to a certificate when the demand for men was pronounced.

Collect $22,000

The government, according to the third annual report of the Department of Labor, collected upwards of $22,000 in fees for engineers' certificates and plant owners' registration certificates. This amount should adequately cover the cost of administration and both the public and the engineers of the province have a right to expect an efficient and fair enforcement of the act for their money.

The examinations for provincial certificates should be wholly for the purpose of ascertaining whether a candidate has sufficient knowledge and experience to properly perform the duties an engineer of his class may be called upon to perform, and as this requirement is primarily for the protection of the public, every man in charge of a plant for which a certified engineer is required under the act should have the necessary certificate, except those continuing in positions they held before the act came into force.

Qualifications Vary

With regard to qualifications required from candidates for second class certificates it is to be noted that an apprenticeship of at least two years as a stationary engineer, erecting engineer, machinist, boiler maker, or blacksmith is required, or the candidate must have completed at least a two year course in Science or Engineering in any university.

What about the two year student of steam engineering in a technical school? Surely the student of a good technical school has as good a foundation in knowledge and experience for this work as has the two year blacksmith apprentice.

What is the standing of the marine engineer under existing regulations, as a ship can hardly be regarded as a building, and the definition of plant given might be used to bar him from a certificate regardless of his knowledge, his experience not having been gained in a "steam plant" within the meaning of the Act.

A comparison of the Ontario and Quebec requirements for the various grades of certificates shows that in the latter province the requirements in the way of operating experience are much larger than in Ontario and it is felt by competent Ontario engineers that this province could well afford to model the requirements upon the lines of the Quebec Act.

How Heat is Produced by Combustion of Coal

This Paper, Written by a Well Known Canadian Engineer, is the First of a Series to be Given as Part of the Educational Program of the Canadian Association of Stationary Engineers

COMBUSTION or burning is defined in "Experimental Engineering" as "any kind of chemical combination evolving heat." It explains further that "the only kind of combustion used to produce heat for engineering purposes is the combustion of various kinds of fuels with oxygen."

There is nothing very enlightening in the definition unless something is known about physics and chemistry, therefore it is necessary to take some time here to explain how these sciences are mixed up in the burning of coal.

There is more or less water in all coal, which begins to come off as vapor, just as soon as the coal is placed in a hot furnace, and, because water boils at 212 deg. Fahr., most of the water in the coal is evaporated as soon as the lump reaches that temperature. A physical change takes place. The heat of the water is raised till it has suffered a "change of state," but it is still water, and if allowed to condense again, it becomes a liquid.

Molecule Smallest Part

The smallest portion of any substance is called a "molecule" which means "a small mass." The molecules of water may exist as ice, water or steam. The change of state does not change them, except to increase their activity if they become gas or to slow up their motion if they become solid matter.

The chemist examines every substance to see how it is made up. His idea is to know matter in its simplest forms and learn how to combine these simple forms to make up various substances. He can prove for instance, that the molecule of water is made up of hydrogen and oxygen, both of which are gases under ordinary conditions.

Also that in all of the substances in daily use there are only some eighty elements from which it is impossible to get any other substance.

For the practical chemist, the smallest unit is called an atom, which means "can't be cut, indivisible." If no more than one kind of atom can be gotten from a substance, that substance is called an element. Atoms or elements do not usually exist alone, but form partnership with others of their kind to form a molecule.

Two quite different substances may unite to form a third entirely different from either. If they do, the process is carried on atom by atom, and the results are exact in every case.

Forms Carbon Monoxide

If a molecule (two atoms) of the carbon in coal is placed where a molecule (two atoms) of the oxygen of the air can get at it, and the temperature is high enough, each of the atoms of the carbon partnership immediately leaves his brother for one of those of the oxygen partnership because they have greater liking or "affinity" for the atom of the other than for their own. They enter into "chemical combination" to form carbon monoxide (CO), a substance which is entirely different from either.

Just why the atoms of one element should have such a decided preference for the atoms of certain other elements, but want a mere acquaintance with those of a second element, and have no liking at all for those of a third element, has never been explained.

It is a fact just the same, and follows along such strict lines that laws are based upon them, and it is possible to tell what will happen when one element is brought into contact with another at the right temperature.

For example, it is known that immediately one atom of carbon is reached by two atoms of oxygen at a temperature of from 755 deg. Fahr. to 925 deg. Fahr., two molecules of CO_2 ($2C+2O_2=2CO_2$) are formed.

When water is changed to steam, many heat units are necessary to effect the change, and this heat will be given out when the water is condensed again. Likewise, heat is "evolved" or produced when water is turned to ice. In the same way heat is a factor in every chemical combination which takes place. The plants and trees which were growing several million years ago were taking CO_2 from the air to make our coal. This CO_2 was decomposed by the heat of the sun, the carbon being retained by the plants, while the oxygen was returned to the air. When that carbon in the form of coal is placed on grates and air brought into contact with it, just as many heat units are given back as were used up in the leaves of the ancient trees.

What has just been stated will explain the fact frequently made in engineering books, to the effect that all the heat of our fuel came from the sun. It did, indirectly, for as has been said, the sun supplied the heat for the chemical action which could not have taken place unless there had been a supply of heat available.

Some idea of the quantity of heat supplied by the sun may be obtained by estimating what heat the combustion of the coal will produce, for the amount produced is equal to the amount absorbed in the years long gone by.

It may be explained here also that although in our every day work it is customary to speak of the number of B.t.u. per pound of coal, the heat units are not actually in the coal. What is meant is that if the coal is brought into contact with oxygen at the right temperature, a chemical reaction will take place in which just so many B.t.u. per pound of coal fired will be produced.

Heat cannot be explained. All that is known is that when energy in this form is applied to a substance, the molecules move more rapidly, and when heat is removed, they slow down. If we apply heat until the substance reaches a certain temperature, solid material will change to a liquid or gas and atoms are likely to hook up with oxygen to form new substances.

Action takes place between the constituents of coal at any temperature. Only a small amount of heat is developed at ordinary temperatures, but coal that is allowed to lie exposed to the weather for several years will lose enough heat to make an appreciable difference in its heat content.

If a fire starts in the coal pile, it is because the heat is confined and the temperature builds up to the point where the heat evolved in the chemical reaction is greater than that lost by conduction through the surrounding coal.

At a Temperature of	Substance	Symbol	Equation
	Carbon	C	$2C+O_2=2CO$
766	Fixed Bit. Coal		$2C+2O_2=2CO_2$
870	Fixed-Semi-Bit. Coal		
925	Fixed-Anthracite Coal		
1210	Carbon Monoxide	CO	$2CO_2+O_2=2CO_2$
1130	Hydrogen	H	$2H_2+O_2=2H_2O$
470	Sulphur	S	$S+O_2=SO_2$
			$S+3O_2=2SO_3$
1202	Methane	CH_4	$CH_4+2O_2=CO_2+2H_2O$
900	Acetylene	C_2H_2	$2C_2H_2+5O_2=4CO_2+2H_2O$
1022	Ethylene	C_2H_4	$C_2H_4+3O_2=2CO_2+2H_2O$
1000	Ethane	C_2H_6	$2C_2H_6+7O_2=4CO_2+6H_2O$
	Hydrogen Sulphide	H_2S	$2H_2S+3O_2=2SO_2+2H_2O$

This phenomenon occurs in lighting a fire, heat is applied to a portion of the fuel until chemical action begins and the heat released is sufficient to raise the temperature of the surrounding fuel till the process goes on of its own accord.

Moisture Driven Off

If heat is added to a single lump of soft coal the moisture begins to vaporize at once, and the water is for practical purposes completely driven out by the time the temperature of the coal has reached 212 deg. Fahr.

Molecules in the coal are caused to move much more quickly than before, and the hydrocarbons begin to come away in the form of gas. This continues till a piece of coal is at a red heat through and through.

The gases are not all driven off at the same temperature, nor do they ignite till they are raised to a very much higher temperature.

As all the combustibles in our lump of coal should produce heat, it is necessary to arrange the furnace so the temperature is high enough to ignite every different compound coming from the coal. Also, the right quantity of air has to be supplied when the ignition point is reached.

This is not as easy as it sounds, for a lump of soft coal weighing one pound is only about four inches square. Even if the arrangements are so good that it will take only 12 pounds of air for its perfect combustion, this air will occupy approximately 163 cubic feet of space.

Suppose this 163 cu. ft. of air (more or less) is passed over the small lump of coal during the time it takes to heat it through and through. The great difficulty will be to do it, without supplying too much or too little oxygen for proper chemical combination.

The lump is lying on the grate with spurts of gas coming from it here and there. These gases mix with the air arising through the grate and combustion may or may not take place in the space above the lump, all depending on the temperature.

Like a Sponge

Suppose that half its actual volume is driven off the lump of coal in the form of gas. How does the rest burn? It is probable, though I have never seen any explanation of the process, that the molecules of the fixed carbon are in such violent agitation due to their heated state, that the lump of coal is like a sponge and the oxygen gets right through it.

The heat from the combustion of the fixed carbon keeps the gases moving straight up unless the draft pulls them in other directions.

Consider first the case where they do mount straight up. If conditions are exactly right, the body of burning gas should take the same shaped form as the flame of a candle, although the edges will be somewhat jagged. The molecules in this body of gas are highly heated and according to their nature they rush along in straight lines, so that each molecule comes to the outside eventually and is mixed with the necessary air for combustion.

It might be assumed, without being so very far wrong, that they travel straight upwards. That would insure that each molecule got enough air to burn just where it reached the surface of the body of flame. If the distance is great enough and the temperature high enough, any quantity of gas would be burned eventually.

What happens if some object below the ignition temperature interferes? Suppose the sheath of burning gas is broken by boiler tubes or bits of the shell of a boiler. What is to prevent all the gas inside the cone from escaping up the stack unburned? Not a thing, if there is no heat to raise its temperature to the ignition point again.

It might be advisable to note that owing to the metal being a good conductor of heat, the tubes or shell of a boiler are very little hotter than the contents, which is at a temperature corresponding to its pressure, and therefore cool compared to the gases which should be somewhere above 2,000 deg. Fahr.

So far only a single lump of coal has been considered. If a number of lumps are placed in a row, the conditions remain much the same, for the air flow between the lumps would probably be sufficient to supply oxygen enough for proper combustion.

Suppose one extra lump is placed on top of the row where it is exposed to the heat on all but one side. It is likely that that particular lump will give up its gas faster than any of the others, while the lump below will give up very little less than those along side it which are not covered.

Keep Fire Level

Together the two lumps will produce about as much gas as any other two lumps, therefore double the air will be required just over that spot on the grate than above any other. That spot can only get air through the grate as fast as the others, so it will be dull and send up a smoky flame. This is one reason why the fuel on the grate should be kept level.

GOLDIE & McCULLOCH AND BABCOCK-WILCOX EXPANSION

A complete chain of offices across the Dominion, with a strengthened sales force, and the utmost in plant and service efficiency, will be developed by the amalgamated firms of Babcock-Wilcox & Goldie-McCulloch. The head office will be located in Galt, and the present Babcock-Wilcox office at Montreal will be retained.

This much has been intimated by officers of the new firm, who are busily engaged with organization and expansion plans.

R. O. McCulloch is president of the new company, A. G. Pratt of New York is chairman of the Board of Directors and A. R. Goldie, vice-president. The other directors are Sir James Kemnal, managing director of Babcock-Wilcox, London, England; W. D. Hoxie, of New York, president of Babcock-Wilcox Company of New York; E. H. Wells, of New York, chairman of the board of Babcock-Wilcox Company of New York, and A. W. Atwater, K.C., of Montreal.

Power House Service in Quebec

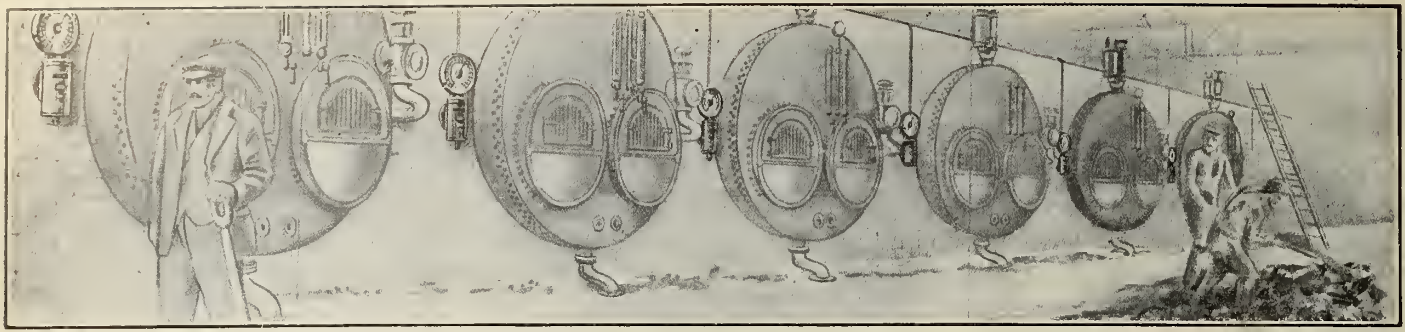
Field Engineer Walter J. Hudson in Montreal to Aid Engineers in Solving Power Plant Problems

RETURNING from a unique service trip to Winnipeg on behalf of Power House, Walter J. Hudson, field engineer, is now in Montreal. That his western trip was such a success Mr. Hudson attributes to the co-operation and assistance of the northern and western engineers, and he wishes to express his appreciation through the columns of Power House. Mr. Hudson feels particularly indebted, among others, to Robert A. Stewart, chief inspector, Bureau of Labor, Winnipeg; W. J. Restall, worthy chief of Winnipeg council, U.C.C. of E.; J. Mills, supt. Grain Exchange Building Winnipeg; William Usher, Engineers' Supply Company, Winnipeg; A. Rusk, chief engineer, Fort William Pulp and Paper Mill Co.; G. W. Exell, chief engineer, General Hospital, Fort William; S. Smith, engineer, Canadian National coal docks, Port Arthur; F. H. Redmile, chief engineer, Central School, Port Arthur; W. J. Ferguson, chief engineer, Thunder Bay Elevator, Port Arthur; W. A. Dedman, chief engineer, Spanish River Pulp and Paper Mill Co., Sault Ste. Marie.

As on his western trip, Mr. Hudson is giving the benefit of his many years' experience in power house problems to all operators who may have perplexing problems to solve or difficulties to overcome in power plant operation.

Few men in Canada in engineering circles have had greater experience than Mr. Hudson, who qualified as a stationary engineer in 1881, and who since that date has filled executive positions with a number of prominent firms in the United States and Canada. His Canadian experience since 1913 has been with such well-known plants as the Moffat Stove Company, Weston, the Standard Sanitary Manufacturing Company and the Coca-Cola Company, of Toronto.

Mr. Hudson is a past master of the A. F. & A.M., and past district deputy of the I.O.O.F. He is a past chief of the Universal Craftsmen Council of Engineers, from which he resigned his position as secretary of Toronto No. 27 on Aug. 27 last.



Easy Engineering Lessons in the Power House

By M. BARRY WATSON, B.A.Sc., M.E.
Director of Engineering, Central Technical School, Toronto.

IN DISCUSSING the generation, transmission or application of power, many people use mechanical terms in the wrong sense or designate mechanical quantities in the wrong units. This is noticeable even among engineers. Of course we must assume that in the case of engineers, such wrong usages are just the result of carelessness or thoughtlessness.

On the other hand most of us do not wish to be considered careless or thoughtless, and it is therefore well for us to check ourselves up from time to time on such questions.

One trouble seems to be that many engineers are too lazy to use compound units of measurement when there is no simple unit of the quantity we are talking about. One of the simplest examples of such laziness or carelessness is in the case of areas. Often we hear such expressions as—so many yards of sheet packing—when "square yards" is meant; or a pressure of so many pounds, or so many pounds per inch when "pounds per square inch" is intended.

Of course everybody knows better than to use such expressions and it is a mere detail, and everybody knows what we mean anyway; but it is the man who is careful about all details who gets along, for if he forms the habit of care in details in his work, he will be careful about details in all his dealings, including his conversation.

An employee's attention to details is often the only characteristic by which an employer is able to judge of his engineer's interest in his work, etc., and it is by the engineer's conversation and written reports that the employer can notice such details.

Clear Up Doubts

There are other quantities, less simple than areas, about which even some engineers seem a little hazy, and it is the purpose of this lesson to try to clear up these knotty problems. The more important quantities of this type in the engineer's work are—force, pressure, work, power, energy, etc.

There is no need of a definition of the word "force." It is merely necessary to mention that a force is measured in pounds, the pound being the force exerted on a unit mass by gravity at sea level. Pressure on the other hand is the amount of force acting on a unit of area, and can be found by dividing the total force acting on the body by the area on which it acts.

Thus the unit of pressure will be the unit of force divided by the unit of area such as "pounds per square inch." The word pressure is often used to designate the total force acting on a body instead of that acting on a unit area. This is not technically correct, but should be designated as "total pressure" to distinguish between it and unit pressure. In this case total pressure really means a force and will be measured in the units of force, or the pound.

Work is defined as "a force acting throughout a distance." Thus if a force is acting on a stationary body there is no work being done, as there can not be work without movement through a distance. The unit in which "work" is measured is the unit of force multiplied by the unit of distance, or the "foot-pound."

Rate of Work

Power may be defined as "the rate of doing work." This brings into consideration the unit of time as well as those of force and distance, making our unit of measurement more complicated still. In expressing speed, or the rate of moving through a distance, we use a unit such as miles per hour, or feet per second, which is the unit of distance divided by the unit of time, or the distance moved by the time taken to move through that distance.

Likewise in determining the rate of doing work, we divide the work done by the time consumed in doing it, thus we may have a unit of power which is the unit of work divided by the unit of time, such as the foot-pound per minute.

The "foot-pound per minute" is a comparatively small unit and if we try to measure very large powers such as are used at the present day by this unit we will find that we should have enormous figures to handle, and one is always more likely to make mistakes in handling large numbers than small ones.

In order to be able to do more of our work in small figures we use a larger unit of power called a "horse-power."

This unit is thirty-three thousand times as big as the foot-pound-per-minute, or one horse-power equals 33,000 foot-pounds per minute. This larger unit is also convenient in that we all can form a better mental conception of a horse-power than we can of the foot-pound-per-minute for the reason that we know what a horse can do, thus in speaking of power in this unit, we get somewhat more of an idea of just what that amount of power is, than when we use the abstract units.

Energy and Power

Energy is "the ability to do work," and since a certain amount of energy is only able to do a definite amount of work, it can be measured by the amount of work it is capable of doing, or in "foot-pounds." Thus it is seen that power and energy, which are so often confused with one another, even by many engineers, are entirely different things and are measured in different units. Power may be defined as the rate of transfer or production of energy.

There are various forms of energy, prominent among which are heat, electrical energy, mechanical energy. These various forms of energy are measured in various units. In the case of heat, the quantity of energy is measured in British Thermal Units, or B.t.u's. This unit is the amount of heat required to raise the temperature of one pound of water one degree Fahrenheit.

It has been found by a long series of scientific experiments that one B.t.u. is equal to 778 foot-pounds, and if we could change heat into mechanical energy without any loss during the change, each B.t.u. would do 778 foot pounds of work. Unfortunately, it is as yet impossible to change heat into mechanical energy without loss.

Introduces Time Element

The rate at which heat energy is being transferred or produced may be considered as a measure of power. This requires the introduction of the time element into the unit of measurement, and power in the form of heat may be expressed as so many B.t.u.'s. per minute or per hour. The term "boiler horse-power" which has been used quite extensively was intended as a unit of heat power, or of rate of heat transfer. This unit has had various definitions, some of which were quite exact in value, while others were anything but definite as a measure of power or capacity to produce power.

Kent in his handbook says "No definite value can be given to this measure, which varies largely with local custom or individual opinion of makers and users of machinery." The most commonly accepted value of the B.h.p. is the equivalent of 33,479 B.t.u.'s. per hour. Converting this to mechanical units it becomes about 435,000 foot pounds per minute, or just over 13 horse-power.

Literally speaking there is no such thing as boiler power, because power is a rate of doing work, and a boiler does not do work, but merely transfers heat units. One should therefore not speak of the power of a boiler, but of the capacity of the boiler.

In electrical work the relation between the units of power and energy is just the reverse of that in mechanical work. In the latter case the unit of power is a compound of the units of energy and time, or is the unit of energy divided by the unit of time, while in electricity the unit of energy is the unit of power multiplied by the unit of time.

The watt or the kilowatt (equals 1,000 watts) is the accepted unit of electrical power, or rate of flow of electrical energy. Therefore the amount of energy transferred in a given time will be the product of the rate of flow and the time, or will be measured in watt-hours, or kilowatt-hours.

The commonly known relation between the electrical and mechanical units of power is, 746 watts equals 1 horse-power. Therefore, one watt equals 33,000 ÷ 746 equals 44.3 foot pounds per minute. One watt-minute will equal 44.3 foot pounds, and one watt-hour will equal 44.3 x 60 equals 2,658 foot pounds.

A mistake which is frequently made is in expressing the capacity of any piece of apparatus in the wrong units. This is especially the case in electrical generators and motors, which are often indiscriminately spoken of in horse-power or kilowatts. The capacity of any piece of apparatus should be expressed in the units in which its product is measured.

The product of a generator is electrical energy, and should therefore be measured in watts or kilowatts, and the machine should be rated in these units. The product of a motor on the other hand is mechanical energy, and therefore the motor is rated in horse-power. It will be noticed that the manufacturers always rate their machines in this way.

To be consistent with this, the capacity of boilers should not be expressed in mechanical units of power, but in heat units, as its output is heat, not power. The Power Test Code Committee of the American Society of Mechanical Engineers recommend that the unit of capacity of steam boilers be "one pound of water evaporated into dry steam from and at 212 degrees F. per hour."

Convention Notes

The 14th annual convention of the National Association of Practical Refrigerating Engineers is to be held in Memphis, Tenn., Dec. 12, 13, 14 and 15, 1923.

Registration headquarters will be at the Chisca Hotel, and S. M. Jackson, P. O. Box 212, Memphis, is chairman of the hotel accommodation committee.

The convention sessions and exhibits will be held in the Scottish Rite Temple on Union Avenue.

Shaw Course Awaits Engineers

Thos. H. Fenner Ready to Give Candidates for Certificates the Knowledge Necessary to Satisfy Examiners

EDUCATION for engineers was one of the strong passions of the late A. M. Wickens and it received a great deal of valuable help from him during his long life. It is perhaps fitting that an act of his shortly before his death was indirectly responsible for the inauguration of a special series of courses for stationary engineers.

The courses referred to are those of the Shaw Schools, prepared by Thos. H. Fenner, and the link that connects Dad Wickens with them arose in this way. An old acquaintance of "Dad's," who had returned to Ontario after an absence of some years, was desirous of obtaining a first-class certificate.

Feeling the need of some instruction before taking the examination, he approached Mr. Wickens with a view to obtaining some advice. Mr. Wickens recommended his friend to Mr. Fenner, and the latter consented to take on "the job." The result was satisfactory, and it was not long before others were applying to Mr. Fenner for instruction.

These enquiries eventually became so numerous that it was impossible for Mr. Fenner to handle them individually, so he decided to place the matter before the Shaw Schools, feeling that their organization was well fitted to handle such a proposition.

Saw Need for Course

W. H. Shaw, the president, and Mr. Chant, the general manager of the school, were quick to recognize the need for such instruction, and decided to place their organization in the field. After careful preparation, the courses are now ready for the engineering public.

The courses have been prepared for the express purpose of enabling candidates for certificates to obtain the knowledge necessary to satisfy the examiners. No claim is made that the course will fit milkmen or any one not already in the power plant engineering field for the responsibilities of power plant operation. The lessons have been prepared for the man who has the amount of practical experience necessary to qualify but who requires aid in expressing his knowledge clearly, and to supplement that knowledge where necessary.

The third-class course consists of ten lectures or lessons, and at the end of each lesson a series of questions for the student to answer are given. These answers will be corrected, and further explanation given where necessary, and any question that may occur to the student will be answered in the same way.

To readers of Power House for the past few years, Mr. Fenner needs little introduction. To new readers it will suffice to say that he has had many years' experience in both marine and stationary engineering, is a member of the Engineering Institute of Canada, a member of the Educational Committee of the C.A. S.E., was for three sessions instructor in power plant engineering at the Central Technical School, Toronto, holds an extra first-class board of trade certificate, first-class province of Quebec certificate, boiler inspector's certificate for the same province, and is at present holding a responsible engineering position in Toronto.

Power Notes

Shortage of common labor has driven manufacturers to an intensive study of the possible economies of material handling equipment in industry. The addition of material handling equipment to the National Exposition of Power and Mechanical Engineering is, therefore, a very timely move, as it furnishes a remarkable opportunity for executives and engineers in industry to study the latest developments in this art. The exposition is to be held in the Grand Central Palace, New York, from Dec. 3 to 8, 1923.

The equipment to be exhibited will include conveyors of all kinds, fireless steam locomotives, industrial trucks, elevators, hoists and large scales. Many novelties are on the list and engineers will have an excellent opportunity to study each type, select the one most suitable for their particular problem and secure the cost data necessary for the decision.

Steel belting for conveyors is a novelty in this country and one exhibitor is to instal a working model of a complete system of steel belting conveyors. The model will be one-tenth actual size. This type of conveyor is well suited for handling sticky materials, sharp-edge materials or materials at high temperature.

The handling of coal at the steam power plant is a severe problem and one exhibitor will show a working model of complete coal-handling equipment in a miniature power house. The model will show a skip-hoist, bunker, coal weigh larry and cable drag scraper.

A program of interesting motion picture films, showing the application of material handling equipment in various industries, will also be displayed.

The power exposition, held annually, features the development of apparatus for the economical combustion of fuel and the production and utilization of power. The managers of the exposition are Fred W. Payne and Charles F. Roth, with offices in the Grand Central Palace.

Electricity in the Power House

By J. A. BURNETT, M.E.I.C., Consulting Engineer, 205 St. James St., Montreal

EXPERIENCES ON THE ROAD

TO BE a successful trouble man, it is necessary to have some knowledge of the design and characteristics of the apparatus causing complaint.

Troubles with apparatus can be divided into two classes—real troubles and imaginary troubles. The latter need not worry the service engineer farther than presenting proof that they do not actually exist. Sometimes the operating engineer has imagined difficulties, but before the discovery of his position he has committed himself, and in order to "make good" he must adhere to his statement that something is wrong. In many cases it is well for the service engineer to act in a diplomatic manner and give the operating engineer an opportunity to withdraw gracefully without injuring his standing with his company.

When the trouble is a real one, then it is wise for the engineer to use caution.

In Unfriendly Mood

Most troubles, before they reach the point where an engineer is sent out, have put the customer in an unfriendly mood, and when the manufacturers' engineer arrives upon the ground, he finds himself received, in many cases, in an abrupt and cold manner. The manager may ask you for an opinion before you have looked over the case, and may show displeasure if you cannot give him an immediate answer. It is best for the service engineer to maintain silence, listen to all that is said, but make no judgment in his own mind until he has made a careful investigation for himself.

The operation of a standard type of alternator, sold with a glowing description to the customer, was far from satisfactory. The alternator was of the well-known compound type, belted to a high-speed engine equipped with a flywheel governor.

Characteristics Known

The characteristics of the alternator were well known. The load was lighting, therefore nominally noninductive, and the exciter was of ample capacity.

The report on this installation stated that at times great difficulty was experienced in keeping up the voltage, that the exciter was heavily overloaded and that two exciter armatures had been damaged.

Several electrical engineers had experimented with the machine and had secured no satisfactory results, therefore it was not a very welcome job for the service engineer. However the plant was visited and as usual the same cold reception given.

The plant was started and everything ran well. The alternator held voltage with a large margin on the rheostats and the exciter was quite cool to the hand. The alternations were approximately correct with the engine running about 250 r.p m.

In a half hour, however, the condition had changed. The alternator could barely hold voltage, with all the rheostats out, and the exciter, laboring under a heavy overload, was quite hot.

A different hum from that at the start of the machinery was heard, so the speed of the unit was taken. The engine was found to be running not at 250 r.p.m. but at 217 r.p.m.

This explained everything. There was a defect in the engine governor which caused the speed to drop at a certain load and to remain there. After this defect was remedied, the engine held speed and the electrical apparatus proved to be in every way satisfactory.

Source of Trouble

The centrifugal pump driven by an electric motor is sometimes a source of annoyance, and the motor receives the blame. The purchaser will tell you that anyone can calculate the power required to drive a pump, but the electric motor is an incomprehensible piece of apparatus and therefore must be the part at fault.

One installation, driven by a 20-h.p. direct connected motor, should have required about 12 h.p., but the motor ran so hot that frequent shutdowns were necessary to permit the motor to cool down.

Actual tests showed that the pump took approximately 33 h.p. and that two-thirds of the required power was expended in churning water.

This pump was adapted for a much higher head than that under which it was operating, resulting in a very low efficiency and its attendant evil, high power for a given load.

Four large alternators in a certain plant would not maintain voltage beyond a load of two-thirds of the capacity of the units. Upon meeting the manager, he desired a clear explanation of the difficulty before an investigation could be made. Of course, an intelligent reply to his questions was im-

R. O. McCULLOCH.

R. O. McCulloch, who heads the new firm of Babcock-Wilcox & Goldie-McCulloch, held the post of president and treasurer of the Goldie & McCulloch Co. He is also a director of the Canada Machinery Corporation and president of the Galt Art Metal Co. A graduate of Toronto University, Mr. McCulloch was called to the Ontario bar in 1888. He is at present a member of the executive of the Canadian Manufacturers' Association.

Mr. McCulloch assumes the presidency of the new firm with a wealth of practical experience in the business fields of Canada, and an executive ability of unquestioned worth.

possible and he would not accept a statement that the cause was not known yet, but took the view that something was being hidden from him.

Preventing Flux Passage

Proceeding quietly with the work, taking a saturation and regulation curve, according to the methods in vogue at that time, it was soon discovered that something was preventing the passage of the magnetic flux through the armature coils.

This, of course, directed attention to the air gap and pole tips. It was noted that the field bobbins were at a distance back from the tips and that the tips were unusually close together.

Acting upon the theory that the lines of force must be held in and driven through the armature iron, the coils were dropped close to the armature.

The immediate effect was that 25 per cent. more load could be carried than before with maintained voltage. The generator still was not up to the guarantee, so to strengthen the pole tips still more, the back fourth of the field bobbins was cut out and the field current increased 25 per cent.

This accomplished the result desired, and the puzzle was solved; but troubles were not yet over.

Going to the manager, we explained that the trouble lay in the field bobbins and that we wished to return them, one set at a time, to the factory to be changed, but he, thinking he had not been treated right, denied the favor, at the same time acknowledging that the machine was not satisfactory nor accepted by him.

A survey of the situation brought our erecting engineer to the conclusion that this was all a case of bluff and trying to get even with the company; therefore, it was resolved to stop one machine that night.

A complete set of bobbins was out of the plant and in a box car before daylight the next morning.

Operation Satisfactory

Of course "blue smoke" rolled about our heads next day, but after the return of the bobbins from the factory and the machine was put into service again it was so satisfactory to the operators that the manager gracefully acknowledged that he had been beaten.

In a selling office, much "charity" and "missionary work" is necessary. For example, a customer reports that his motor is burnt out; an investigation shows that perhaps a fuse is blown or the power off the circuit. Another reports that his motor is grounded, which means that he had a static discharge coming from the belt.

Recently a customer thought something was wrong because the voltage on a compound direct-current generator increased when the load came on instead of decreasing. He had always been used to the voltage decreasing with the increase of load, and any other condition he reasoned to be wrong.

Induction Motor Troubles

Many remarks could be made as to induction motor troubles, the principal one being worn bearings, permitting the rotor to drop and resulting in "firing" at bottom and damage to stator coils.

A rough-and-ready test is to set a wood block under the motor pulley and to use a wooden pry to work the pulley up and down. Any slight movement being visible, it can be determined at once if the bearing is worn or not. The remedy is to repair the bearings or replace with new.

A. R. Goldie, who assumes the office of vice-president of the Babcock-Wilcox & Goldie-McCulloch Co., has been manager of the Goldie & McCulloch Co. since 1897, succeeding his father, John Goldie. Mr. Goldie is a graduate of Toronto University, School of Practical Science. He joined the Goldie & McCulloch Co. in 1895 as assistant manager and in 1917 assumed the position of vice-president of the firm.

Mr. Goldie is not only a practical mechanical engineer but a business man of unusual ability, who adds infinitely to the strength of the new firm.

A. R. GOLDIE.

PIPE LINES

UNCOVERED IN ANY OLD SPOT

The ostrich whimpers in distress,
And takes it rather ill
That he, indeed, is killed to dress
The girl that's dressed to kill.

* * *

Exhaust pipes should always be water-jacketed. A number of fires have occurred by oil leaking out of the fuel lines and striking a red-hot exhaust pipe. It is never advisable to use a water jet inside the exhaust pipe. If sulphur is present it will eat the iron pipe.

* * *

A cat has nine lives;
But isn't it right
That a frog's just as good,
For it croaks every night?

* * *

In starting a Diesel the cylinders should not be oveprimed; if the starting cylinders get much fuel, there may occur a pre-ignition resulting in a bent connecting-rod or fractured cylinder head.

* * *

Women's faults are many;
Men have only two—
Everything they say, and
Everything they do!

* * *

The crankshaft-bearing housings on all modern engines are bored true to within 0.001 inch. The bearing shells are bored to size so that the crankshaft must be level if the base is level.

* * *

Two engineers were talking. The first said: "That fireman you're had working for you asked me for a job this morning. Was he a steady chap?"

The second engineer answered: "He was. If he'da been any steadier he'da been motionless."

* * *

A Diesel driven flour mill will produce a barrel of flour at an expenditure of 0.55 gal. of fuel oil, 0.006 gal. of lubricating oil, and with 1 cent of repairs. The total power cost including fuel, repairs, wages, etc., is 9 cents per barrel.

An optimist is an engineer who wears a white vest and carries a fountain pen that is so constructed that it won't leak.

Practical Ideas From Practical Men

CONTROLLING FIVE PUMPS

IT MAY be of more than passing interest to readers of "Power House" to know how, with a little effort and perseverance, we succeeded in practically cutting in two, in our plant, the work of tending the pumps shown in the diagram. Nos. 1 and 2 are boiler feed pumps, pumping from the heater to the boilers; No. 3 is a standby, to pump either boilers, heater or storage tank; No. 4 supplies an overhead storage tank for both mills and four furnaces; and No. 5 supplies water to the heater.

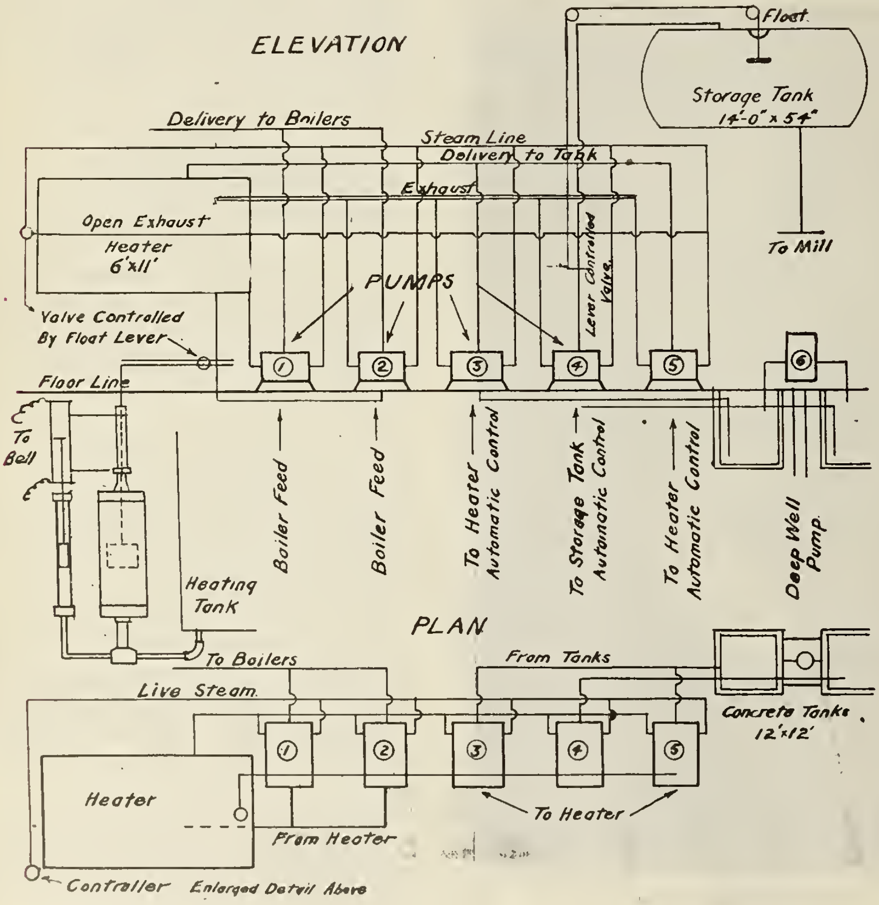
These pumps were not supplied with governors, but had to be controlled by hand with considerable guesswork, as most of the time the watertenders would be out around the boilers, which are pretty well scattered over the mill and some distance from the pump room. The overhead storage tank is rather small, the delivery being 4 ins. and the main outlet 5 ins., feeding close to 50 branch lines of ½, ¾ in., and 1 in. pipes, all of which or any number, may be running at the same time.

The watertender has no control over these outlets except to keep water in the tank.

It often happened that the tank would become empty, causing a delay in both mills as they cannot run without water. The same thing happened to the feed water heater occasionally. Sometimes the heater was fed too fast, the tank filling up, resulting in a loss of heat, as it was supplied with exhaust steam. When the heater was empty, the pumps would run away through lack of water, and when the water rushed into the heater again, there was a tendency to wash up mud, which would go into the pumps and thence to the boilers. The storage tank overhead had a wooden float in it to indicate the amount of water.

One day I ran across an old 1 in. globe valve with a sliding stem, and decided to fix it up. Our blacksmith forged a steel yoke for it, a lever being attached to the yoke and stem.

The valve was then installed in the steam line and by means of necessary pulleys and about 40 ft. of small chain, the pump was made to run automatically from the storage tank. This was about 15 months ago, and it has not failed once since. As a check on its performance, another float was put in the tank for a gauge.



I then wanted to run the heater automatically, but the tank was so full of large trays that a float could not very well be put in it, so I conceived the idea of tapping the bottom of the tank and attaching a chamber to work the float.

The chamber was made from 8 in. pipe nipple with couplings at each end and bushed to 1 in. about 20 ins. overall. A round tin float was made about 7 ins. in diameter and 9 ins. long, a small pipe attached and levers to operate a valve similar to the other.

The steam line was taken around the heater and back again to Nos. 3 and 5 pumps, and after making necessary adjustments, we were able to maintain a half a glass of water steadily in the heater.

I was not altogether satisfied with this, so a 2 in. pipe of the same length as the other, was attached to the bottom of the chamber and another smaller float about 1¾ ins. diameter and 10 ins. long, made. Two ¼ in. nuts were soldered on top and a ¼ in. wooden stem screwed on it. A copper blade was fastened to the top of the stem, the blade travelling between two more fixed contacts, one for high water and one for low. The float was then wired up for an electric gong.

Now, instead of the heater getting too full or empty, it maintains a constant level, and when the water reaches a predetermined point from its normal level, through failure of its float arrangement to work, the smaller float operates the gong, there is still 6 ins. of water in the bottom of heater giving us time to attend to it before it is empty.

An old buzzer which was lying around and doing no useful work, was taken and a blade carrying ink soldered to the arm. It was then fastened inside the box of a recording voltmeter and wired to the gong circuit.

The buzzer draws a circle on the chart, and when the gong rings puts a line at right angles to the circular line, plainly indicating any movement of the buzzer and recording the time.

These two tanks in the past, required careful attention, and were the cause of much worry. All troubles have been eliminated. ARTHUR H. LACEY, Manitoba Rolling Mill Co., W. Selkirk.

REPAIRING A BEDPLATE

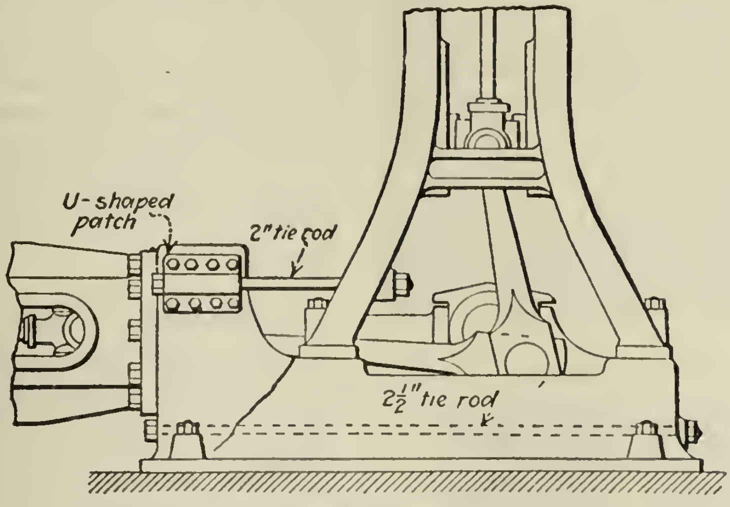
Owing to a slug of water passing into the cylinder along with the steam, the bedplate of a horizontal engine driving a vertical ammonia compressor was cracked as shown in the illustration. The damage was repaired by drilling two 2⅝-in. holes in each end of the bedplate and clamping it together with 2½-in. tie-rods.

The rods were heated to a dull red for about 18 in. in the middle of their lengths before they were inserted. Washers, one of which was beveled on one face to conform to the taper at the outer end of the frame, were slipped over the rods, and the nuts were pulled up tight. As the rods cooled, the ends of the bedplate were drawn together until the fracture was almost invisible.

The machine was then put in service, but after it had been run for a day or two, it became apparent that the staying afforded by the through-rods was not sufficient. It was then decided to tie the engine-bed to the A-frame supporting the compressor cylinder. Accordingly, two 2 1/16-in. holes were drilled in the A-frame and a U-shaped patch was fastened with 1½-in. capscrews to each side of the bed forming the guide yoke. The U-patches were then clamped to the A-frame with 2-in. tie rods. These bolts were also heated in the middle to a dull red before putting them in place.

This job of patching was at first intended to be only temporary, as it was planned to replace the broken bedplate with a new one at the first opportunity. But the repair job proved to be so substantial that all thought of replacing the bedplate was finally abandoned.

—WALTER J. HUDSON.



Broken Bedplate.

ENGINE LINER TROUBLES

Herewith is a rough sketch of the H.P. cylinder of a triple-expansion engine of 500 h.p., which I had charge of some time back. The engine gave very little trouble but began to develop a "hault" in its movement, which appeared to be in the H.P. engine.

I shut the engine down and lifted the H.P. valve over, feeling certain that the root of the trouble was there, but alas, on drawing the piston valve, everything was "O.K.," so I closed up the valve chest and opened the cylinder, but as the H.P. piston appeared all right I closed up the cylinder and started up again "to have another look at her."

I had no indicator, or the first thing I should have done would have been to take a set of cards which would have immediately shown up the defect, but a brilliant idea struck me while watching the engine struggling around. I opened the indicator cocks; the top cock discharged steam full bore, and the bottom cock made no response. This, along with the gradual dropping of I.P. and L.P. receiver pressures, caused me to form the opinion that there was something radically wrong with the H.P. engine.

The cylinder liner was steam-jacketed, the heating steam passing through the jacket before entering the coils of a H.P. "feed heater."

The liner was a fixture in the bottom fitting strip of cylinder, but was free to expand lengthways in the top fitting strip. The top end was fitted with a copper expansion ring A, which allowed for expansion and at the same time maintained a steam-tight joint between jacket and cylinder.

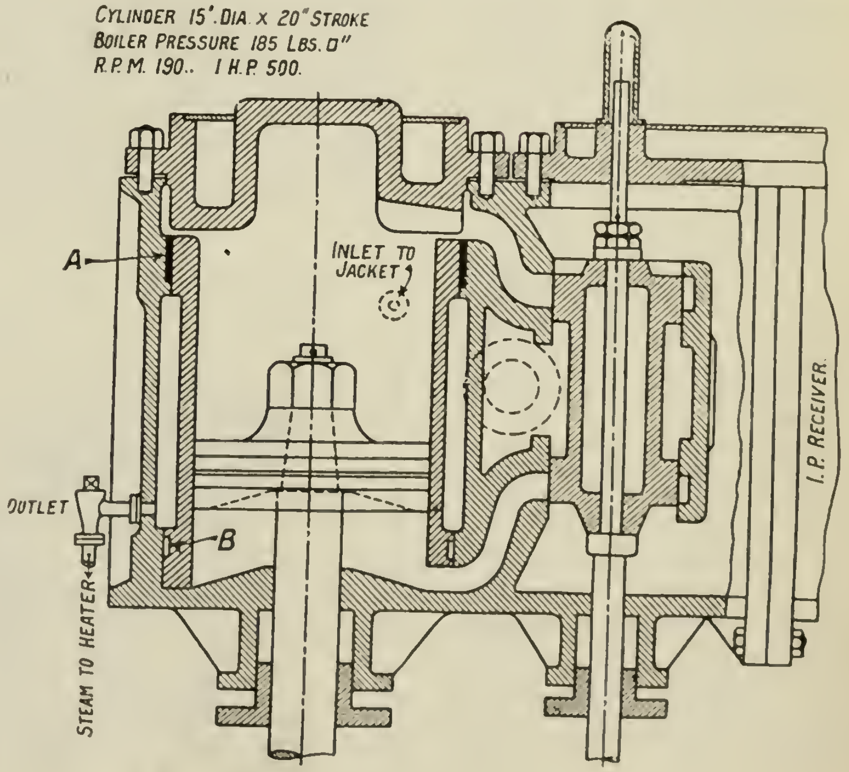
On the cylinder being again opened, the inlet valve to heating jacket was accidentally left open, thus allowing steam to escape round expansion ring, showing liner to be slack, but as there were no marks on lifting bolt holes, I couldn't see how much the liner had moved. Two ⅝-in. eye bolt holes were drilled in liner end, and on the weight being taken up on a set of blocks, the liner lifted clean out of the cylinder.

It was then discovered that the lower end of liner had been a poor fit in bottom fitting strip, also there was about 1/16 in. clearance between liner end and cylinder cover and evidently the liner had moved up and down with the piston, and at the same time turned round sufficiently to nearly close the bottom port.

The defect was remedied by turning a groove 2 in. at B and deep enough to take 1-16 in. copper wire, leaving a good projection. This was wound firmly on and sweated with hard solder, and after being filed up to allow for a good fit, was shrunk into cylinder body; the copper ring, which remained in top fitting strip, was then caulked up, and on being tested everything was found "O.K."

Incidents such as described above tend to show the amount of trouble that may be averted by the frequent use of an indicator, the defect in itself being of quite a simple nature, but the average engineer would just have soon thought of looking for a bag in the steam pipe as a liner turning as stated.

A. TREAVES



Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

LOST PUMP MOTION

How is the pause obtained at the end of the stroke of a direct duplex steam pump?

—OTTAWA ENGINEER.

Ans: The pause is obtained by valve-rod clearance, commonly called "lost motion," which is obtained in various ways.

Fig. 1 shows how the clearance usually is provided on small pumps. A valve rod nut (a) is placed on the rod (b) inside of the steam chest, the nut being thinner than the space (c) between projections on the top of the valve. Either the diameter of the nut is made large enough to prevent its turning on the rod and adjustment is made by turning the valve rod, or jamb nuts are used. In this design the total lost motion is fixed and the lost motion (J) at either end, cannot be changed except by use of a nut or jamb nuts of different thickness.

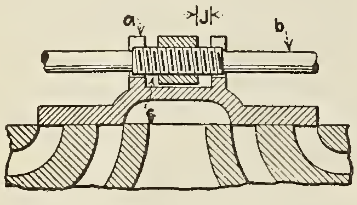


Fig. 1, Inside Fixed Lost Motion

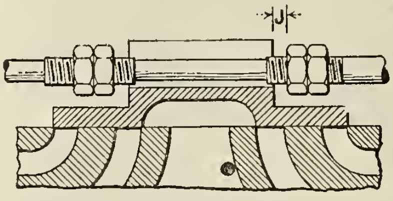

Fig. 2, Inside Adjustable Lost Motion

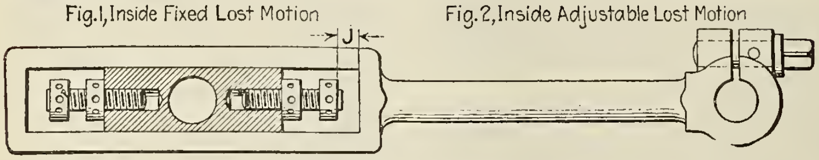

Fig. 3, Outside Adjustable Lost Motion

In Fig. 2 the lost motion is adjustable both in amount and distance (J) at either side by changing the position of the jamb nuts on the rod on either side of the valve, although the pump must first be stopped and the steam-chest cover removed.

On large pumping engines that are operated by skilled attendants, the clearance is provided in an outside adjustable lost-motion link, Fig. 3, in the train of connections between the valve and its rocker. One end of the link is slotted for carrying a sliding block, shown in cross-section, and the lost motion (J) at either end of the block is readily adjusted by tappets secured by check nuts, by means of which the lost motion for either end of the valve can be modified while the pumping engine is running.

BOILER TUBE LEAKAGE

During periods of shortage of anthracite, we have burned bituminous coal for our return-tubular boilers, and whenever it is used we are troubled with leakage of the tube ends in the rear tube sheets of the boiler. How can this be remedied?

R. WYLIE.

Answer:—The trouble undoubtedly results from incompletion of combustion in the furnace combined with carrying of coal dust to the back connections where the combustion is completed, resulting in exposure of the tube ends to extraordinary heat. This may result from stoking too much coal at a time and undertaking to force the boilers with insufficient air supply. If there is a strong draft, particles of coal may be carried into the back connection and burned there in place of burning on the grates. This may be largely prevented by wetting down the coal before it is fired.

CORLISS ENGINE PIN

For starting a Corliss engine, why is it necessary to have the governor raised with the collar supported on the starting pin, and why will the engine run away if the belt breaks with the starting pin left in place?

A. READER.

Ans.:—When the governor pin is out, the engine cannot be started from rest because the governor is down so low that the safety cams prevent the steam valves from being picked up. When the governor is raised to a position in which it is supported on the starting pin, the safety cams become moved around to a position that permits the valves to be picked up.

Then with the throttle valve open and enough steam pressure for moving the piston, the engine can be started fast enough to carry the crank over the centre, and the engine will continue to move faster until cut-off comes into action.

Should the governor belt break with the starting pin left in, the governor could not fall to a low enough position to bring the safety cams into a position that would prevent the valves from being picked up, as when starting up, and, unless the load chanced to be very much in excess of normal, the engine would run away.

SEMI-DIESEL CAPACITY

Why will a semi-Diesel engine cylinder of a given stroke develop more power with than without water injection?

—A. R. HUGHSON.

Ans.:—The introduction of water into the cylinder during the scavenging part of the stroke serves to lower the temperature of the hot piston head and cylinder walls. The air, on entering the cylinder, does not heat up so much. A greater weight of air will then be trapped in the cylinder and, since the power output depends upon the weight of air present to be combined with the fuel, the water enables the engine to burn more fuel and develop more power.

TRAP DISCHARGE

When a tilting trap dumps from the weight of water in the trap, what would be the reason for failure of the water to be discharged from the trap?

Ans.:—The trap would fail to discharge either from stoppage of the discharge connections or from more back pressure on the discharge than the pressure maintained within the trap. The latter condition would exist if the trap received the condensate from a vacuum system with the discharge open to the atmosphere; or if the pressure of returns received from a heating system were insufficient to overcome the pressure required for overcoming friction of flow plus the pressure against which final discharge must take place.

OPERATING MOTORS

Will you kindly advise if overmotoring a load when using direct current causes a waste of power? We need a 7½-h.p. motor and have for disposal a 30-h.p. motor. The size of this motor does not cause us inconvenience as far as floor space is concerned, but would the large motor be less economical, first cost not considered, than the smaller motor?

—WINNIPEG BOY.

Ans.:—The full-load efficiency of a 7½-h.p. motor is about 85 per cent. A 30-h.p. motor carrying this load would be operating under 25 per cent. load and its efficiency under this condition would be about 77 per cent., leaving a difference of 8 per cent. in favor of the 7½-h.p. motor. Of course, this will vary with the type and speed of the motor, but the figure is a fair average value.

Using the foregoing figures and assuming that the 7½-h.p. motor operates under full load, then its power consumption is 7.5 × 746 ÷ 0.85 = 6,582 watts. To carry this same load on the 30-h.p. motor would require 7.5 × 746 ÷ 0.77 = 7,266 watts, or a difference of 7.266 — 6,582 = 684 watts in favor of the small motor. Assuming that the motor operates eight hours a day for 300 days a year gives 684 × 300 × 8 = 1,641,600 watt-hours, or 1,642 kilowatt-hours.

If power costs, say, 4c. per kilowatt-hour, then the saving for the year by installing a 7½-h,p, motor would amount to 1,642 × 0.04 = $65.68. Of course, this saving will vary with the cost of power and the load on the motor.

It ought to be possible to dispose of the 30-h.p. motor for a price equivalent to that for a new 7½-h.p. machine. If this can be done, then the saving in power will be a net gain.

STEAM PUMP PORTS

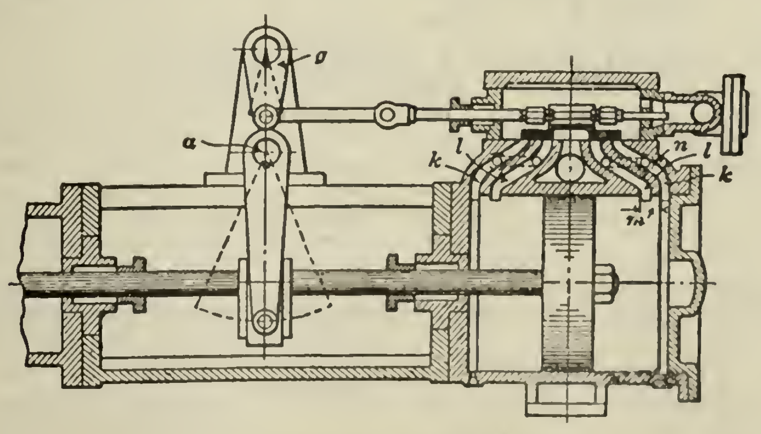
Why is each steam cylinder of a duplex steam pump provided with five ports? —HAMILTON B.

Answer:—The outer port at each end acts as a steam admission port and terminates at the end of the cylinder so as to guide the incoming steam into the clearance space behind the piston, while the ports nearer the middle or central exhaust passage act only as exhaust ports. When the piston is near the end of the stroke, it covers the exhaust port.

Any steam then remaining in the end of the cylinder and the connected steam passages, is entrapped and, becoming compressed by the piston, acts like a cushion in overcoming the momentum of the piston and thus brings it quietly to a stop without striking the head of the cylinder.

The arrangement of the ports is illustrated in the figure, showing a vertical section through the steam end of the left-hand side of a duplex pump, with the piston, valve rockers a and g, and the D slide valve in heavy shading, all shown at mid-travel. The outer ports k are the steam ports and the other passages are for the exhaust. The distance m from the outer edge of the exhaust port to the head forms the cushion.

On pumps having more than 10 in. stroke, a passage is usually provided between the ports k and l and a valve n is inserted, which can be opened for the escape of part of the exhaust from the port k to the exhaust port l, should the piston cushion too heavily.



Section Through Steam End.

UTILIZING WASTE HEAT

Will you kindly work out the approximate saving which would be effected in a boiler plant by the utilization of 257,100 lb. of water at 190 deg. F. per week at present running to waste?—REGULAR READER.

Answer.—Very few particulars are given by "Regular Reader," but assuming certain factors, he will be able to work out the correct coal saving as follows: Boiler assumed working at 100 lb. gauge pressure, with steam temperature 337 deg., the sensible heat = 308 B.T.U. and latent heat 877 B.T.U., and total heat required to raise 1 lb. of water from 32 deg. F. to the above pressure therefore = 308 + 877 = 1,185 B.T.U.

If the present feed-water supply to the boiler be taken at 50 deg. F., 1,167 B.T.U. are required to raise each pound of water from 50 deg. to steam at 100 lb. gauge pressure. We can further assume the calorific value of the coal used at an average figure of 12,000 B.T.U. per pound, and 6½ lb. of water evaporated per pound of coal from 50 deg. to steam 100 lb. gauge. The total heat available in the weekly supply of hot water = 257,100 lb. at 190 deg.; therefore, 190 — feed-water temperature of 50 deg. = 140 deg. 257,100 × 140 deg., approximately 36 million B.T.U. Correcting these figures—

$$\frac{35,994,000 \text{ B.T.U.}}{1,167 \times 6\frac{1}{2}} = 4,879 \text{ lb. coal per}$$

week; or weekly saving in coal of two tons three and a half hundredweight. A small amount of steam will be required to deliver the hot water to the boilers, reducing this figure to approximately two tons per week.

Colonel H. D. Savage, of New York, director, Pulverized Fuel Division, Combustion Engineering Corporation, will deliver a lecture before a meeting held under the auspices of the Ontario section, American Society of Mechanical Engineers in the Mining Building, Room 22, University of Toronto, on Nov. 27. Colonel Savage has been intimately connected with the development of pulverized fuel from its infancy and is a frequent contributor to the technical press on this subject. The more efficient utilization of our fuel resources is a matter of national concern and this comparatively new development promises to be of value in the burning of many coals not readily amenable to ordinary methods.

Can YOU Qualify for that Good Job?

HAVE you got a First-Class Certificate? You cannot get very far, cannot make the most money, until you have passed **every** examination. To-day it is easy to prepare yourself for any Certificate Examination. T. H. Fenner, former editor of "Power House," will train you by mail in your spare time through Shaw's Course in Stationary Engineering. There's a big demand for qualified men. Comments in the Power Plant Field

UNVARNISHED TRUTH

The Editor,
Power House.

Regarding the letter in a recent issue of Power House, "Some New Theories" by Robert McLaren, I quite agree with that engineer's remarks that the design of the furnace has much to do with completed combustion of coal.

Many engineers know that there is a greater waste of coal going on from some chimneys that do not show black smoke, than from those that do. Carbon monoxide gas is invisible, therefore it is impossible for any man to know when it is escaping out of the stack unless he is provided with the necessary flue gas recording instruments and draft gauges. Such instruments are as necessary these times of dear and scarce coal, as steam gauges for indicating the pressure inside the boilers.

This is not theory; it is plain, unvarnished truth, but how difficult it is to cause some owners of boiler plants to realize it! The day may dawn when to conserve our coal the powers that be will make all large users instal devices for saving coal, and also require that the recording charts be forwarded to a department provided by the provincial government, with penalties for infraction of laws provided.

Cut Fuel Costs

By such means the consumption of coal would fall greatly. As demand creates price, it should be a money saver for the consumer.

When acting as inspector of boilers, I have come across sights that would bring tears to one's eyes. The following are a few instances: 50-100 H.P. multitubular boilers set with only sixteen inches between top of grate and the underside of boiler. The top of fire bridge wall six inches from boiler, and encrusted with clinker, fused into the brick, leaving only 2-3 inches of opening. The space between the floor line and underside of boiler at rear of bridge wall filled in to a depth of 7 inches for gas travel, thereby not only not providing any combustion chamber or gas pocket, but actually causing the products of combustion to impinge on the water wall of boiler.

In some cases, the temperature of the induction water is 160 degrees lower than boiling point. We are aware what the temperature of the flue gases must be in in order to unite with the incoming oxygen and burst into flame. Under such conditions, how is it possible for those products of combustion to retain anything like the temperature at which they left the bed of fire?

Throttling the Gases

I have also seen cases where only seven inches of space was allowed between the end of a multitubular boiler and the rear wall, thereby further throttling the gases and carrying them to be retarded and held up to the cold shell of the boiler for a longer time than necessary. 24-28 inches would be better for this chamber.

A higher efficiency with less fuel is obtained when boilers have been raised forty-eight inches off the line of grate. If we place our finger momentarily in the flame of a lighted match we do not feel as intense a heat as when the finger is held one or two inches above the flame. The same remarks apply to the burner of a gas cooking stove. Better results with less gas will be obtained by having a space of four to five inches between flame and under side of kettle.

When it is stated that Canada uses up $100,000,000 worth of fuel per year, and that there are thousands of cases where from twenty-five to thirty per cent. of fuel is unnecessarily burned, it is obvious that the money value of such waste could be applied to more useful purposes. Some may ridicule my estimate of the waste. Cases have been recorded when taking a steam evaporation test showing that fifty per cent. of the coal was being burned to waste.

When Pipe is Hot

Not long ago, I asked the caretaker of a building heated by hot water how he knew when the water was hot enough to suit the outside temperature. He took me into another part of the building and placing his hands on the overflow pipe from an expansion tank, said "When that pipe is hot I check the fire."

Every engineer is aware that before an expansion tank will overflow and cause boiling water to come down that pipe, the radiators are too hot, especially if the outside air is only twenty degrees lower than the inside air, which was the case on that day. Apart from the waste of fuel, such management is apt to cause very considerable air or vacuum after cooling down, which means more fuel unnecessarily burned in order to have the radiators circulating efficiently.

A thermometer connected into the waterway of the heater or header at a cost of a few dollars would have saved considerable money each day in fuel.

—J. S. KINGSTON, A.M.A.S.M.E.,
Ottawa.

VALVE INSTALLATIONS

During years of experience in power plant work, including pipe-fitting, I have profited by the mistakes of others. Some of the mistakes in question have been fully described in the pages of Power House, but the following instances have to do mainly with valve work, many valves on new work being made worthless by careless workmen at the time of installation.

Even the experienced man sometimes applies a wrench to the hexagon farthest from the pipe when screwing on the valve, a proceeding which is liable to distort the valve body. If it is a globe or gate valve refacing it may prove a cure if the "twist" is not too great. Irrespective of the style of valve, however, it should be closed when being screwed on the pipe and its rigidity will be slightly increased.

To look at some pipe-fitting jobs, a person gets the impression that the erector had taken particular pains to so place the hangers that the valves would be compelled to assume a great deal of the strain due to weight, expansion and contraction. All such harmful strains can be prevented, as far as the valves are concerned, with reasonable care.

Even at this date some pipefitters will persist in painting the threads inside of valves and fittings instead of applying the paint or grease to the pipe threads. Since paint or grease is sticky, if it is allowed to lodge in valves, (disk, gate or other design) it will catch grit, such as pipe scale, etc., and the first time the valve is operated the grit may cut the valve enough to make it leak.

Steam should be blown through a new line of pipe for a longer or shorter period, depending upon the length of the line, its size, and the pressure of the liquid or steam. The longer this blowing can be maintained the better, even though it extends to half an hour. Of course, reason and common sense must be used; a six-inch steam main with a high pressure could be left open for only a short period. All valves on the line should be opened wide before the blowing is started.

In pipe-fitting it is safer to use a short thread on the pipe than a long one when connecting brass valves. In the latter case, the pipe end may shoulder against the valve seat and injure the valve beyond repair. I have seen men place a long wrench upon the bonnet of a valve, a six-foot length of pipe on the handle of the wrench, and then a couple of men at the other end of the pipe—a long pull, a strong pull, and a loosened bonnet and a permanently distorted valve. Probably the wrench alone with one man and no pipe could have loosened the bonnet if a jerking jarring pull had been used instead of a steady pull.

Very often a tight bonnet can be loosened by tapping it with a hammer and applying the flame of a blow torch around it for a minute or two. The slight expansion is enough to crack the fried, hardened paint, or other dope. I have seen valves permanently injured by the workman attempting to screw in the bonnet with the stem and disc in the closed position, with the result that the disc reached the seat before the bonnet was down, thus causing a bent spindle and a sprung seat.

The Wellman-Seaver-Morgan Co., Cleveland and Akron, O., have arranged for the Newport News Shipbuilding & Dry Dock Co. to take over the hydraulic turbine business of the Wellman Co. This includes patterns, drawings, data, patents, inventions, records, etc.

The Wellman-Seaver-Morgan Co. have built numerous large turbines for Canada, including some for the Chippawa development project.

The John Inglis Co., of Toronto, built turbines to the designs of the Wellman Co. Recently three units of about 2,500 h.p. each were shipped to the Nova Power Co., and Mr. Inglis to-day stated that the change would not affect his manufacturing rights as he would now build turbines to the designs of the Newport Co.

The Ottawa Electric Railway contemplates the construction of a $20,000 garage and power house on Albert St., Ottawa.

Thomas A. Marsh, chief electrical engineer of the Combustion Engineering Corporation, Chicago, was the speaker at the meeting of the Manitoba branch of the Engineering Institute of Canada, Nov. 1, in the Engineering Building, University of Manitoba. Mr. Marsh gave a non-technical discussion on "The Combustion of Canadian Coals."

The Hamilton Branch of the Engineering Institute of Canada opened the winter season with a dinner at the Royal Connaught Hotel, Hamilton, Nov. 1. Walter J. Francis, M.E.I.C., consulting engineer, of Montreal, and president of the Institute, in an interesting address, stressed the gravity of the fuel problem facing Canada to-day. The chair was occupied by R. K. Palmer, chief engineer of the Hamilton Bridge Works. Other speakers were: Fraser S. Keith, Montreal; Major Alan Mair Jackson, Brantford; Wm D. Black, of the Otis-Fensom Elevator Co.; Col. N. R. Robertson and J. A. MacFarlane, of the Hamilton Bridge Works.

R. J. Durley, M.B.E., M.E.I.C., secretary of the Canadian Engineering Standards Association, addressed the Ottawa branch of the Engineering Institute of Canada at a luncheon in the Chateau Laurier, Oct. 31. Mr. Durley was professor of mechanical engineering at McGill University for eleven years, and during the war was in charge of gauges and standards of the Imperial Munitions Board. His subject was the standardization of engineering products and the resulting benefits that would accrue to industry from the simplification and unification of manufactured pieces. Mr. Durley said that standardization was not altogether the best word to use and that simplification or unification would better express the objects the association had in view.

The town council, Forest, Ont., is having plans prepared for the installation of a waterworks system, including 3 stage centrifugal pumps, mains, valves, hydrants, tower, etc. Chipman and Power, Mail Bldg., Toronto, engineers. Estimated cost, $100,000.

John T. Farmer, chief engineer of the Combustion Engineering Co. of Canada, was the speaker at a meeting of the Canadian Association of Stationary Engineers, Nov. 6, in the Mechanics' Institute, Atwater Ave., Montreal. His subject was "Flue Gas Analysis and Its Bearing on Economy in the Power House."

The name of the Central Quebec Power Co. is being changed by supplementary letters patent to the Algonquin Power Co. The capital of the company has been increased from $1,000,000 to $2 000 000. These changes are regarded as preliminary to the formation of plans for the development of a power site in Quebec controlled by the company.

for the complete protection of life and property against abnormal steam flow into a damaged boiler or a break in a steam main—you are safe in making the identical selection for your plant. Consider the following features:

1. Automatically cut out the boiler the instant that a tube ruptures or other internal break occurs.
2. Automatically cut off the steam flow from every boiler the instant that a steam pipe breaks.
3. Automatically equalizes the pressure beween all boilers.
4. Automatically cut in a boiler making accidents due to inaccurate steam gauge impossible.
5. Positively prevent backflow of steam into a cold boiler.
6. Can be closed by hand, like ordinary stop valve, and arranged with "combination feature" to open valve like regular gate and globe valve.
7. Can be tested in service from boiler room floor.
8. Double Corliss Dash Pot that cushions in opening and closing.
9. Cannot pound, spin, stick or chatter.

High Grade Power Plant Equipment

Progress in New Power Equipment

A NEW PUMP LINE

A NEW line of steam and belt-driven dry vacuum pumps has recently been placed on the market by the Canadian Ingersoll-Rand Co., 260 St. James St., Montreal.

The belt-driven units are known as the Class ER-1, and the steam-driven machines as the Class FR-1 type. They are similar to this company's ER and FR air and gas compressors and, like the latter, are of the single stage, straight-line, centre crank, dust and dirt-proof type with automatic lubrication of both running parts and vacuum ends.

They embody every refinement of modern vacuum pump design, including a number of features which make them as nearly automatic in action as any machine of this type can be expected to be. This is an important consideration in any vacuum pump, but is even more essential in the case of small and medium-sized units which are often operated in isolated locations where but little attention can be given them.

Large machines, on the other hand, are generally located in a central power house under the supervision of an expert engineer. These machines are recommended for use in canning factories, smelting plants, packing houses and paper mills.

Ensures Steam Economy

The class FR-1 vacuum pump consists of a plate-valved vacuum cylinder direct-connected to a steam engine with balanced piston valve, a design which makes it possible to operate with high pressures and superheated steam as well as the moderate pressures more common in the past. This feature ensures steam economy at all pressures.

The main frame of both types, as previously mentioned, is of the enclosed design, the bottom part forming a reservoir for the combined splash and flood lubricating system. It is fitted with removable side and crank and covers which are not bolted on but are retained by lips on the frame casting. Removal of these covers permits inspection or adjustment of all running parts.

The crosshead guides are of the bored type and the design of the frame provides for an oil stuffing box near the cylinder end of the frame, which prevents any chance of crank case oil entering the vacuum cylinder. Openings in the cylinder end of the main frame and in the trunk piece interposed between the steam and air cylinders on the class FR-1 type provide for adjustment of stuffing boxes when running.

The main frame and trunk piece of the steam-driven units are mounted on a substantial cast-iron sub-base which lends rigidity to the entire structure, makes the machine a complete, self-contained, accurately-aligned unit, and also forms a support for the single rocker arm which guides the valve rod. There are no guide blocks or other sliding surfaces in the piston valve gear.

Little Appreciable Wear

The main bearings are of very heavy construction and provided with removable die-cast shells or liners of genuine babbitt metal which can be removed and renewed in a few seconds, at small cost. Due to the area of the bearings and the complete circulation of oil through them at all times, however, the shells last for very long periods without appreciable wear.

The crank-shaft and connecting rods are solid one-piece drop forgings, accurately machined and heat-treated. The connecting rod is of the solid end type with renewable and adjustable boxes in both crosshead and crank pin ends. The crosshead is of the cylindrical type, of box construction with adjustable bored and turned shoes.

Pistons are of the box type with broad faces and are securely fastened to a turned and ground steel rod.

Oil is distributed to all of the running parts by throwers on the crank webs which lift or throw the oil against baffles from which it runs to all wearing surfaces. This system, now widely used, was originated by this company more than twenty years ago and is probably the simplest, most effective and economical ever devised.

Lubrication of steam and vacuum cylinders is provided for by a double compartment, adjustable sight feed, mechanically operated lubricator.

The piston steam valve is provided with two piston rings at each end and operates in a renewable bushing. With this type of valve there is no rapid wearing or cutting and the valve chest stuffing box is only subjected to exhaust pressure. as steam is admitted to the centre of the valve and exhausted from the ends.

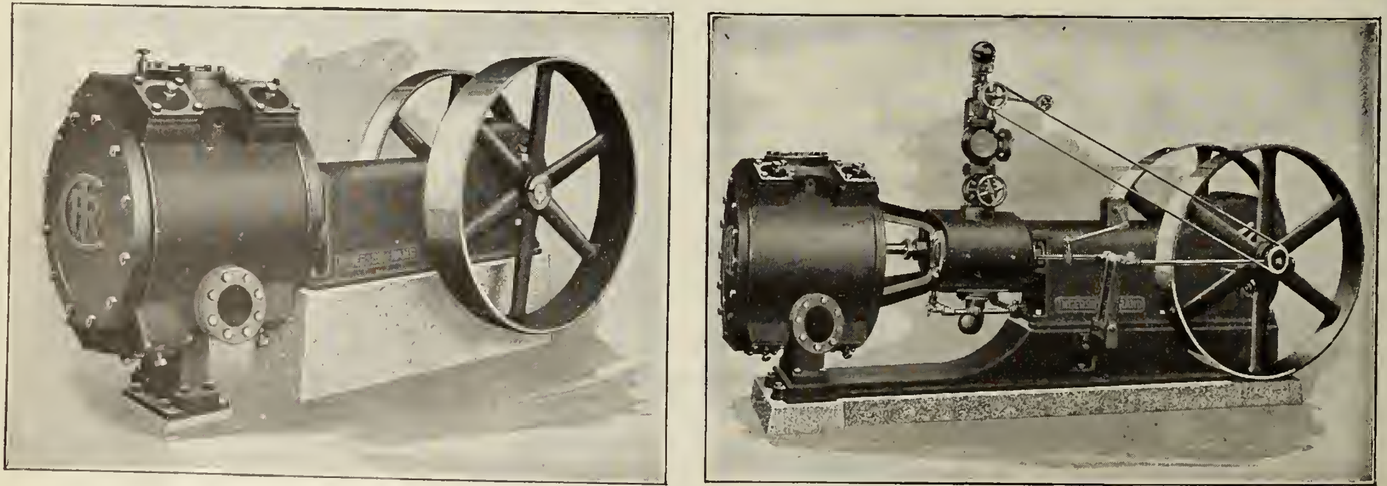
Regulation of the class FR-1 vacuum pump is regularly provided for by an adjustable speed throttling governor, although a "Wide-Range" automatic cut-off flywheel governor is sometimes used.

Saves Floor Space

The class ER-1 belt-driven units are furnished for either long or short belt drive. The latter arrangement is generally preferred as it not only saves floor space but also increases the arc of belt contact and reduces belt wear and bearing load.

Both classes of these machines are built in four sizes with piston displacements of about 500 to 2,300 cu. ft. per minute. They are well adapted for filter pans, evaporator effects and similar classes of service where high and steady vacuum is required.

With closed intakes they will pull up to 1.0 inch absolute, or 29 inches when referred to a 30-inch barometer—this



Ingersoll-Rand Class "ER" Belt Driven Dry Vacuum Pump and Class "FR" Steam Driven Dry Vacuum Pump.

vacuum differing, of course, with the size and stroke of the pump.

High speeds of operation, coupled with the high volumetric efficiency provide greater capacity for a given size of cylinder, resulting in a marked economy of floor space.

The Canadian Ingersoll-Rand Company also announce their bulletin K-315, describing these machines, which are produced at their Sherbrooke plant. This catalogue contains numerous illustrations covering these machines, and should be of value to anyone interested in either belt or steam driven vacuum pumps.

NEW CONTROLLER VALVE

A CONSIDERABLE advance has been made by the Bristol Company, of Waterbury, Conn., in the production of temperature controlling apparatus by the development of the Bristol-Fuller Controller Valves.

This apparatus is intended for use with oil and gas heated furnaces or ovens and is designed to maintain an indicated temperature by controlling automatically the flow of the air, gas or oil to the furnace.

Motor Operation

Both the fuel and air valves are operated by one electric motor. When using the valves for controlling a temperature, both the valves are first adjusted to a low setting, giving a flame of perfect combustion, but too low to bring furnace up to desired temperature.

If an automatic controlling instrument is used in connection with valves to measure temperature of furnace, when set to temperature wanted, a contact will be made which will start the motor. When the valve is opened the motor stops.

With both valves in this position, they may be adjusted to give a high flame of perfect combustion, which will bring temperature of furnace slightly above the temperature wanted, then as soon as the furnace has reached the temperature higher than desired, the instrument will make contact, thus operating the motor and close the valve to the low flame.

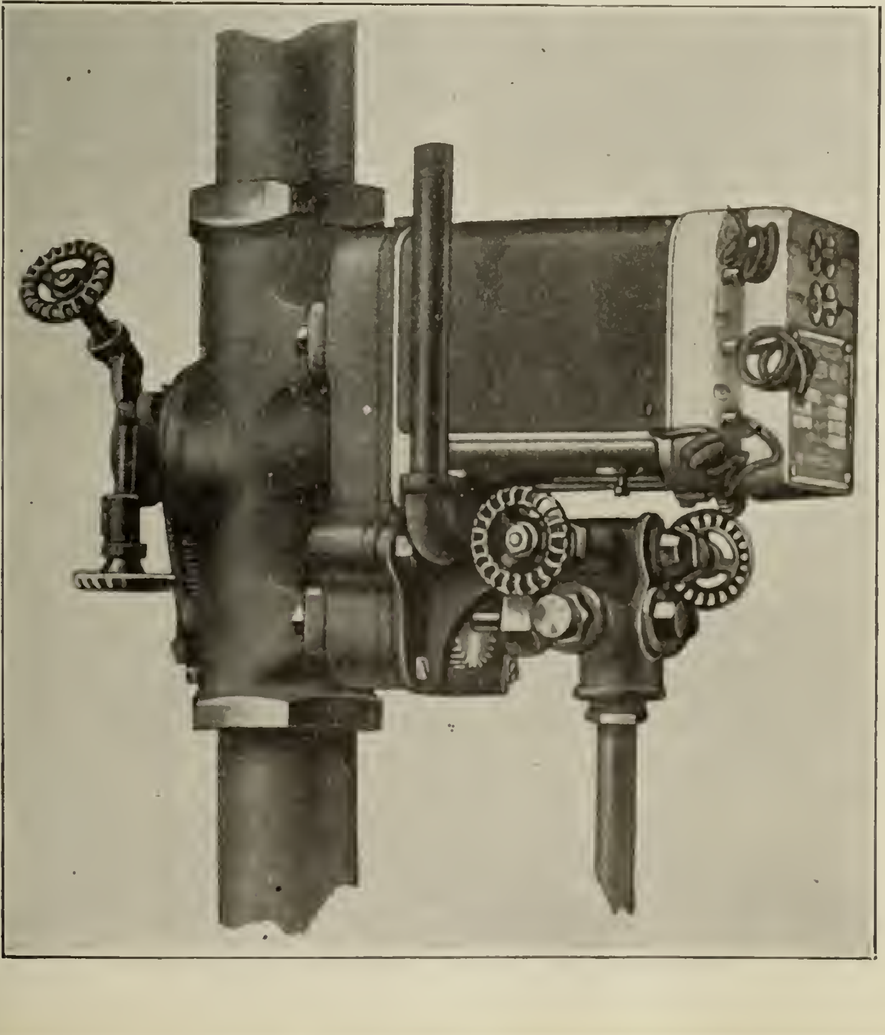
Independent Adjustments

All adjustments of the valves are made independently, and thus, in no way can one adjustment upset any other.

When a sensitive controlling instrument is used, and the high and low flames are correct, it has been found that the furnace assumes the temperature desired.

The equipment consists of the gear box, motor and switch so arranged that any one is readily replaceable. A standard make of motor is used and the speed is reduced in the gear box to operate the crank for the valves.

The valves are opened and closed by crank motions thus the motor is not reversed, but is stopped at the end of



CLASSIFIED ADVERTISEMENTS

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

BUSINESS CHANCES

SMALL BOILER REPAIR BUSINESS FOR SALE—with house property adjoining. No opposition. Located in a large manufacturing city. Reason for selling, owner in ill-health. Apply Box 110, Power House.

POWER PLANT FOR VILLAGE OF TIGNISH About 18 kil. hour capacity 110 to 220 volting alternating current. Apply to John A. Hackett, Box 67, Tignish, P. E. I.

EQUIPMENT FOR SALE

FOR SALE—ONE CANADIAN GENERAL belt driven, direct current generator, 115 to 125 volts, capacity 360 amperes, speed 975 R.P.M's.; also a quantity of used shafting and pulleys. Apply to Box 114, Power House.

SAW MILL MACHINERY FOR PORTABLE medium and heavy mills, band or circular; we build everything for the saw mill from haul-up to sorting table. The Waterous Engine Works, Ltd., Brantford.

TAYLOR SAFE FOR SALE—INSIDE DIMENsions 15" deep, 2 ft. 6" wide, 3 ft. 11½" high. We will accept $225.00 for this safe—a bargain for someone. Apply Box 110, Power House

For Quick Sale

Self-oiling high speed engine, single cylinder 17 in. bore x 16 in. stroke. Engine develops 200 H.P. when running at 235 R.P.M. with 100 lbs. steam pressure. There are two heavy leather belts 18 in. wide. The engine has two fly-wheels, each 78 in. diameter x 18 in. face. Apply **Box 112, Power House.**

PISTON RINGS

EVER-TYTE and ZELCO Piston Rings with Patented Zelco Process Save Gasoline, Oil, Increase Capacity, Prevent Cylinder from Wearing Out of Round, Lessen Carbon; after using, make arrangement with us to sell them; made up to 80-inch; used in Locomotives, Boats, Engines, Compressors, Ice Machines, Autos, Trucks, Tractors, etc.; are looking for distributors with mechanical knowledge; all or part time; real opportunity. Ever-Tyte, St. Louis, Mo.

POWER HOUSE

Solves the Problem

It is a dominating factor in maintaining power plant efficiency in equipment and service.

Every issue teems with advertising and editorial matter of a character that will keep YOU right up to the minute in power plant knowledge.

TWO ISSUES PER MONTH
TWENTY-FOUR PER YEAR
TWO DOLLARS

the stroke of the crank. In order to stop the motor at the high and low valve adjustments, a control switch operated by a cam turned by the motor, is opened.

This switch has two sets of contacts, one in the circuit of high contact of control system, and the other in circuit of the low contact. When the cam breaks one circuit, it makes the other. This cam and switch are housed in an aluminum case.

The case also contains push-button switches, which may be used to operate the valve electrically, without the controlling instrument.

A different type of controller valve is supplied for the different mixtures whether of air and gas or air and oil and varying also with the pressures used. For low air pressures not exceeding two pounds per square inch a butterfly type of valve is used to control the air supply while a globe valve is used with higher pressures.

A SUPERHEAT PACKING

The Steel Mill Packing Company, of Detroit, have placed on the market a sheet packing called Safety Superheat Sheet Packing, and it is claimed that this packing will stand a high temperature, cannot be forced out by high pressure, and will resist the disintegrating influences of heat, oil, acid or alkali.

The packing is a combination of asbestos and rubber with color and mineral fillers giving a compound that, according to the makers, will resist heat to the utmost degree, and which cannot soften, burn, blow or ooze out of the joint. The compound as a whole is said to be water, acid and alkali proof and will successfully resist the action of these agents in the finished product.

The ingredients are thoroughly mixed into a plastic mineral mass and then felted under immense pressure into a compact yet elastic sheet which has been so rolled and compressed that further compression by the flange is impossible. A gasket, once inserted, requires no following up.

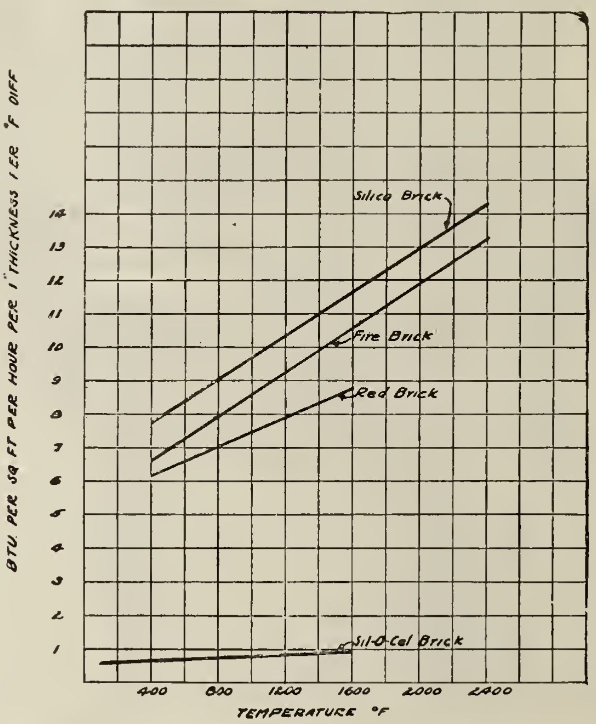
This company also manufacture the Safety Elastic Metallic Packing for use with steam, water, gas and hydraulic machines and valves. This packing is made of an alloy of the best anti-friction metals, combined with the finest lubricating materials, and is practically self-lubricating and frictionless, and, according to the makers, will stand steam pressure up to 550 deg. Fahr., and hydraulic pressure up to 5,000 lbs. per square inch.

NOVEL DATA SHEETS

The Celite Products Company have recently instituted a novel method of distributing engineering data on their heat insulation products. For the convenience of engineers who may use that form of engineering data, they have reproduced many of their blueprints and charts in sheets, punched and ready for insertion in standard looseleaf binders.

These include charts showing comparative conductivities of Sil-O-Cel brick, red brick and refractories, as well as heat losses through wall constructions, insulated and uninsulated, and drawings showing methods of insulating such equipment as boilers, furnaces, ovens, brick, lime and cement kilns, gas equipment, glass equipment, oil stills, etc.

The sheets are not intended to replace the regular literature and standard size blueprints, but the number of requests received indicates their popularity for ready reference purposes. Copies will be gladly sent Canadian engineers on request.



Conductivity of Sil-O-Cel Brick, Red Brick and Refractories.

SAFETY FACTORS IN HIGH-PRESSURE BOILER DESIGN

(Continued from page 26)

steam entering the attemperator was at a somewhat higher temperature than the steam discharged. It was found entirely practicable to hold the temperature within a range of, say, 5 deg. or 6 deg. Fah. between the highest and lowest points by spraying a regulated amount of water into the superheated steam. The apparatus consisted of a vessel containing water placed in the exit pipe conducting the superheated steam away from the attemperator.

Generate Definite Pressure

There was a definite pressure generated in the vessel for each particular temperature through boiling the contained water, and this pressure acted on a diaphragm and actuated an apparatus for admitting more or less water to the superheated steam. The temperature of superheated steam that could be handled in this way was limited to, say, 650 deg. Fah. For higher temperature than this it was proposed to use mercury in place of water in the vessel.

Shortly after experimenting with the attemperating device, the idea was applied to an independently fired superheater as a superheat limiting device, where, on the temperature rising to a given point, doors were opened in the setting for admitting cold air. This arrangement proved to be entirely reliable through trials made every twenty-four hours, where the temperature was purposely raised to the point for which the apparatus was set.

An interesting feature developed, as it was found possible to operate the independently fired superheaters much more closely through observing the pressure in the vessel containing the water than by reading a thermometer. The vessel consisted of a coil having a considerable surface in contact with the superheated steam in proportion to its volume, and an attached pressure gauge indicated changes in temperature much more effectively than a thermometer, as the change in pressure due to the boiling of the water was greater than the corresponding change in the temperature.

For example, raising the temperature from 490 deg. to 500 deg. Fah. resulted in raising the pressure 62 lb. per square inch, so that there was a change indicated by the pressure gauge of about 6 lb. for each 1 deg. Fah. It was found that the superheater could be operated at such a constant exit temperature through observing the pressure gauge that a recording thermometer placed on the outlet gave practically constant readings.

An apparatus of the sort could be used either for attemperating the steam and holding it at a given temperature, or it could be used as a limiting device to reduce the superheat in an emergency without attempting to maintain the temperature of the steam at a given figure.

In the latest boilers for high-pressure and high-temperature superheated steam built by the Babcock and Wilcox Company, the superheater is placed above a series of tubes in a drop leg and below the main body of tubes of the boiler.

A superheater properly arranged in this position in a properly designed boiler gives a more constant degree of superheat at different ratings than if placed in the ordinary position above the boiler tubes and permits a higher degree of superheat to be obtained with a given amount of superheating surface, and for the temperature of superheated steam now employed the superheat obtained with a superheater of the sort is near enough constant for use without an attemperating device.

There is but little gain in the economy in increasing the steam pressure to a higher point than 350 lb. per square inch without interstage heating of the steam; that is, the steam from one stage of the turbine must be withdrawn from the turbine, re-superheated and returned to the following stage of the steam turbine.

MOTOR TROUBLE IN POWER PLANTS

(Continued from page 29)

large expense for lamp renewals, as a new lamp would burn out within a few hours. The engineer was undecided as to what was the cause of the trouble, not being very well versed in electrical work.

Finally, an electrician connected with the company which supplied the plant with current was called in. He soon located the trouble with a portable voltmeter, for the voltage on one leg of the circuit was 138, while the other leg was around 90. The trouble was eliminated by the installation of a suitable balancer coil.

Book Reviews

Kent's Mechanical Engineer's Handbook. By the late William Kent, Tenth Edition. Rewritten by Robert Thurston Kent, editor in chief, and a staff of 35 specialists. Published by John Wiley & Sons, New York City, 1923. Limp binding with gold edges; 4¼ x 7 in.; 2,247 pages with tables, curves and diagrams. Price: Genuine leather, $7; Atholeather, $6.

This handbook is not merely the tenth edition of the late William Kent's work. It is truly a new "Kent," rewritten to bring it into line with recent engineering practice With slightly larger type pages and with 700 more of them, the new Kent contains over fifty per cent. more material than the ninth edition.

A casual inspection reveals at once a great wealth of new material. Useful tables, in particular, are supplied in greater profusion than ever. The book is divided into 27 main sections, each with its own table of contents.

Every Engineer, Mechanic and Electrical Worker will welcome this new master set. It will answer your problems.

It will help you with your daily work.—A sure source of advancement and higher pay. Complete up-to-date information that is thoroughly and easily explained on every branch of modern engineering and electrical practice.

Generator Insurance
Premium:- Part of ONE Man's Time!

Dusty, dirty cooling air for electrical equipment is a real hazard, making easy short circuits, fires, and serious damage.

Insure yourself by using CLEAN AIR from Midwest Air Filters. They have no moving parts, sprays, pumps, nor anything to get out of order. The first cost is practically the last, because the only operating costs are a few minutes by one man for cleaning and a small amount of fluid for charging.

Have you sent for data book, F-15?

MIDWEST AIR FILTERS

Anti-Clinker
SHELL-BAR GRATE BARS

Designed and built by men with practical experience, the Shell-Bar Anti-Clinker Grate Bars are built to

Get the last bit of heat out of the last bit of fuel

Maximum air space permits perfect combustion even of low-grade fuel. Nothing is burnt to waste—nothing is wasted in clinkers. Wherever they are used they are giving more heat with less fuel.

Write for full particulars

Hays Improved Gas Analyzer.

Are You Wasting Fuel?

Numerous Canadian power plant men correctly answer that question by using the HAYS IMPROVED GAS ANALYZER. Rugged, portable, fast, accurate and INEXPENSIVE, it is the acknowledged leader of Flue Gas Analysis Instruments. Made in two styles. 3-chamber Analyzer for CO_2, O_2 and CO; 1-chamber Analyzer for CO_2 only. Stocked by Canadian Agents listed below.

LINDE

REFRIGERATING AND ICE MAKING MACHINERY

For Refrigerating and Ice Making Plants Large and Small

Vertical Enclosed Type Machines made for capacities from one to fifty tons.

Horizontal Frame Heavy Duty Type Machines made for plants up to 300 tons capacity.

LINDE Machines embody every improvement that adds efficiency and durability, and are the ultimate development of specialized engineering and manufacturing experience during fifty years.

All present-day Linde Machines are fitted with our patent silent valves, giving increased efficiency and guaranteed to be mechanically silent in operation.

Linde Machines will do the most work for the least money.

The Linde Canadian Refrigeration Co., Ltd.

37 St. Peter Street, MONTREAL, Que.

TORONTO WINNIPEG VANCOUVER

"Yes, Madam, Your Husband was a Careful Investor"

Will your banker be able to give your widow this assurance?

YOU do not save money for the mere joy of having it. You have a definite purpose in view. It may be to protect your own later years; to educate your children and start them out in life or to sustain your widow and dependents should you yourself pass on.

For these purposes you save —and invest what you save. It is a sacred trust. To fulfill it you must put that which you save where it will be safe, first, and produce a good income, second. You do this by investing.

Only carefully made investments will achieve your ends. Careful investing requires reliable information.

You can get this necessary sound information and advice weekly in The Financial Post.

Nine thousand other Canadian business men subscribe to it and look to it for news and advice concerning stocks, bonds, mortgages, insurance and business policies in general.

Do the same yourself. Subscribe to-day. Lay the foundation of your fortune on the solid rock of knowledge.

When you have filled in this coupon and attached your cheque for $5 you have assured yourself of 52 issues full of meaty, intelligible, readable business and investment news. Better do it now.

THE FINANCIAL POST,
143 University Avenue, Toronto.

Send me The Post for one year (52 issues).
I enclose $5 (or you may draw on me).

FLEXCO
TRADE MARK
Lamp Guards

You'll Soon Need Guards

Guard every lamp that is in danger of breakage or unauthorized removal. Protect yourself from losses and accidents. Flexco and Flexco-Lok (patent locking) guards cost less than new lamps. Last for years.

Expanded metal re-enforced construction. Attractive in appearance. Very rigid and strong. Made with key locking or plain round head screws. A style for every lamp.

Free sample 50 watt guard and complete information sent on letterhead request, mentioning socket size.

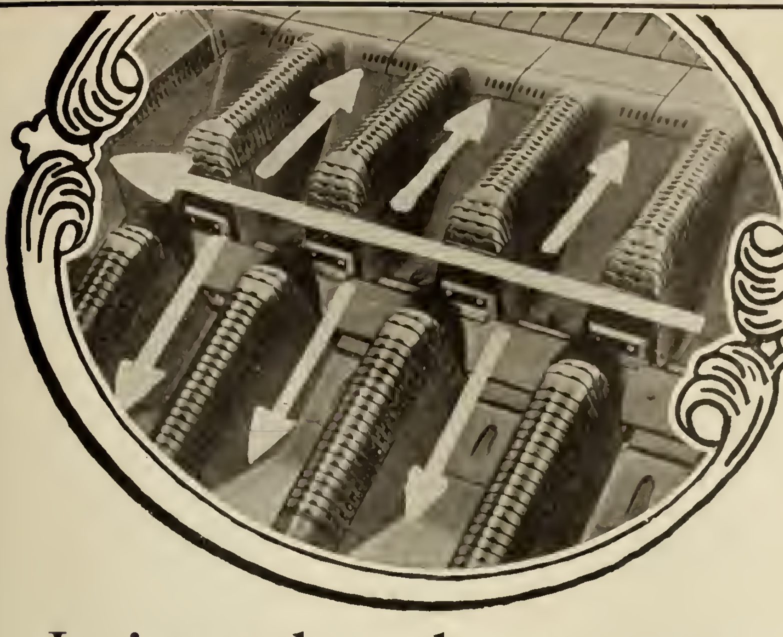
Does your equipment provide Efficiency ?????????

"POWER HOUSE," edited by Canadians for Canadians conversant with Canadian conditions, is the one logical medium for you to use in order to influence Canadian trade your way. Twice a month Power House will carry your message to power plant owners and operators, fresh every issue; and at a time when THEY ARE OPEN for guidance on matters relating to Power Plant Efficiency in Management, Equipment, and Operation.

ADVERTISE YOUR PRODUCT TO CANADIANS

Our experience proves to us that "Power House," the Power Plant Journal of Canada, is a dominating factor in establishing and maintaining a favorable interest and attitude on the part of the Canada buyer towards efficient power plant equipment.



RILEY JONES

The
UNDER-FEED
STOKER
COMPANY
OF CANADA
LTD.

MURPHY

It introduced a new era in underfeed stoker firing—

THE coming of the **"Lateral Retort"** Stoker brought a new epoch in stoker building—and a welcome one. It made available for every plant the high efficiency and high capacity of the multiple retort stoker at the installation and operating cost of the single retort stoker.

Although the **"Lateral Retort"** is multiple retort in effect, in construction it is a simple, single retort stoker. Coal, following the path of the arrows, is first underfed to the main retort and then, actuated by lateral pusher blocks, is underfed into the **"lateral retorts."** Finally, the ash is deposited upon easily operated side dump plates and is dropped into ash pits only 6 to 18 inches below the floor line—so shallow that no expensive ash pit construction is needed.

Ask for the **"Lateral Retort"** Bulletin that shows how this stoker is multiple retort in everything but price—how perfect coal distribution is obtained because of the control of the fuel bed afforded by the main ram and the auxiliary ram—how high efficiency is obtained because of the application of the underfeed principle—how heavy overload capacity is secured by great reserve capacity—how automatic control of fuel and air is given by the use of the Cole Automatic Valve—how features of construction give long life and freedom from excessive maintenance costs.

Your Copy of the Booklet awaits your postcard

The Under-Feed Stoker Co. of Canada Ltd.
146 King Street, West - Toronto

Sales agents for "Jones" Stokers, "Riley" Stokers and "Murphy" Automatic Furnaces

British Columbia: E. A. Earle, Ltd., Vancouver, B C

Quebec: The Cleaton Co., (Can. Ltd.,) Montreal, Que.

Advantages of the *"Lateral Retort"* Principle

Coal is underfed throughout not overfed on to side grates. This is the only truly *underfed* side-cleaning stoker.

One simple moving unit for five or more retorts—The feeding mechanism of the *"lateral retorts"* is controlled independently of main feed, permitting ideal fuel distribution under all conditions.

Simplest cleaning mechanism—a perfectly balanced dump plate easily operated by hand.

No need for basement ash pits—a trench 6 to 18 inches below the floor line is sufficient excavation for ash pits. This greatly reduces installation cost and makes the stoker adaptable to boilers already in service.

Plate tuyeres—reduce siftings and lower replacement cost.

High air cooled front and rear tuyere blocks keep fire and clinkers away from front wall and bridge wall, reducing furnace maintenance.

The "Lateral Retort" Stoker

MORRISON

Pressure Reducing Valves

Efficient — Reliable

J.M.T. Flanged Reducing Valve.

J.M.T. Reducing Valve—Iron Body Bronze Mounted.

To allow for the unequal expansion of the metals, the bronze body lining is suspended from the centre leaving a space between the lining and the body.

Non-Equalizing

Extremely Sensitive.

Nothing could be more positive than the action of the J.M.T. Pressure Reducing Valve in which the low pressure is controlled by the low pressure steam. When the desired low pressure has been obtained the low pressure steam closes the valve. Its simple, automatic effectiveness is the result of years of experiment.

J.M.T. Reducing Valves are made to suit every requirement and are sold with the well-known Morrison guarantee.

"Every Installation is a Demonstration of Merit"

J.M.T. Reducing Valve, differential type, iron body.

J.M.T. Reducing Valve—Low Pressure.

For reduced pressures under 5 lbs. per sq. in. The large diaphragm provides ample power to operate the valve on very low pressures and make the valve sensitive to the slightest change in the reduced pressure.

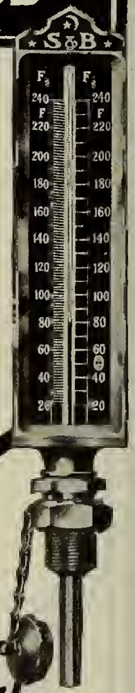
Accurate Measuring of Temperatures-

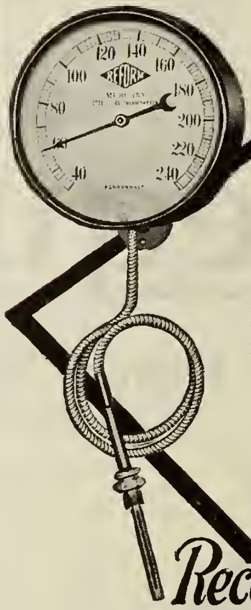


Thermometers of questionable accuracy are a source of real danger.

Schaeffer & Budenberg Thermometers are *guaranteed* accurate. And over seventy years of thermometer-making experience is at your service, gratis, in the solving of your temperature measuring problems.

Crescent Thermometers

For every industrial need. Made in any range up to 1000° F.



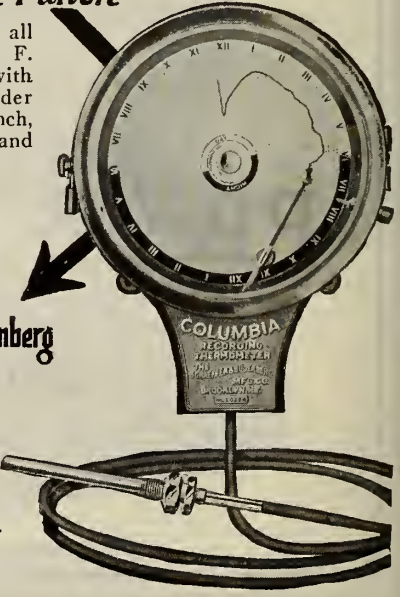
Reform Mercury Dial Thermometers

have the accuracy of the glass thermometer and the reading convenience of the dial face. Indicating dial may be mounted at any point convenient for reading. For temperature ranges up to 1000° F. With 4-in., 6-in. and 12-in. dial.

Columbia Recording Thermometers

with the Time Punch

For accurately recording all temperatures up to 1000° F. Mercury actuated. Fitted with that wonderful new recorder improvement, the Time Punch, which tells how often and when the chart is read.



Let us prescribe and quote on your Thermometer needs. You will find our Catalog N 33 instructive. A copy is yours for the asking.

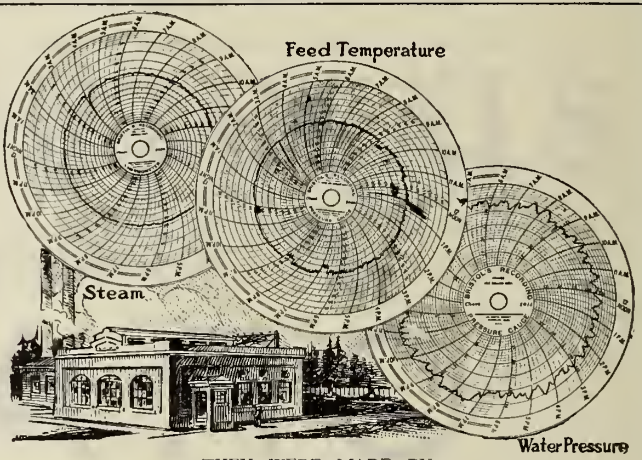
The History of One Day on these Three Charts

At the Winona Public Utility Company Plant.



THEY WERE MADE BY

TRADE MARK
BRISTOL'S
REG. U.S. PAT. OFFICE
RECORDING INSTRUMENTS

and analyzed by the plant owners, as follows:

"The steam chart gives us a record of the steam pressure 24 hours per day. The fireman knows that we have a record of the steam pressure and holds the steam where it should be at all times. He also knows that we have a record of the feed water temperature, and by a glance at the chart he knows if this temperature drops and goes after the trouble, which means a saving of fuel. The water pressure gauge shows the water pressure at all times, which is supplied by a motor driven centrifugal pump operating 24 hours per day. This chart makes a record of any excessive water consumption by a slight drop in the pressure. We have some 2 inch services, which when opened reduce the pressure about 10 lbs. You will also note at 12:30 noon a fire broke out and the fire pump was put on the lines for about 20 minutes which raised the pressure to about 115 lbs. From 9 o'clock at night to 4 o'clock in the morning you will note the chart to show an almost straight line as very little water is used this time of night."

Above:

"Jones Standard Side-Dump"

Opposite:

"Jones Lateral Retort"

No expensive ash pits needed with these stokers

TWO types of "Jones" Stokers that can be installed without expensive ash pit construction, bring low installation cost to practically every Canadian plant.

The "Jones Standard Side-Dump" is installed under boilers to 200 h.p. or thereabouts—the "Jones Lateral Retort" under boilers of larger size.

Both types bring the high efficiency of the superior "Jones" under-feed principle. They make "Jones" under-feed stoker firing available for every Canadian plant.

In both types the ash is deposited on side dump plates. It is then dropped into shallow ash pits below, which need be no deeper than six to eighteen inches.

Don't you want the entire story of these cheaply installed "Jones" Under-feed Stokers? Then ask for the free "Standard Side Dump" or "Lateral Retort" Bulletin. A post card will bring either.

Two-Stage Ammonia Compressors
With Clearance Control

THE Clearance Control used on I-R two-stage, direct-connected, electric motor-driven ammonia compressors provides for:

- Operating at full, three-quarter, or one-half rated capacity;
- Adjusting the capacity of your compressor to take care of reduced winter loads;
- Operating the compressor with either low or high suction pressures;
- Starting and stopping the machine in gradual steps, resulting in less severe motor duty, and eliminating fluctuation in the electric lines due to throwing the load "all on or all off."

With the Ingersoll-Rand "Clearance Control" the clearance pockets are cast integral with the high and low pressure cylinders. Opening the clearance pockets in both cylinders maintains, at all load points, a constant ratio of compression and equal balance. When operating at partial loads the horse power required is reduced practically in direct proportion to the volume of gas delivered.

Other features of these compressors include:

Ingersoll-Rand Plate Valves for intake and discharge. Two-stage Construction (with water intercooler where desired). Enclosed Frame Construction and Automatic Lubrication.

Nonpareil Corkboard with Armstrong's Mastic Finish on the walls of the Polar Ice & Coal Company, Louisville, Ky.

Armstrong's Mastic Finish

A M F—Armstrong's Mastic Finish—is designed to be used instead of cement plaster in all cold storage rooms where moisture conditions are unusual. Such are ice storages, beef and pork chillrooms, coil lofts and bunkers, sharp freezer anterooms, etc.

Armstrong's Mastic Finish is a mineral rubber compound an eighth of an inch thick ironed on Nonpareil Corkboard **at the factory.** It is dense, tough, flexible substance, perfectly impervious to air and moisture. Applied hot and soft, it is keyed into the surface under heavy pressure eliminating all air holes and bubbles. It has no odor. It does not become brittle or crack when cold, nor does it soften or peel at ordinary temperatures.

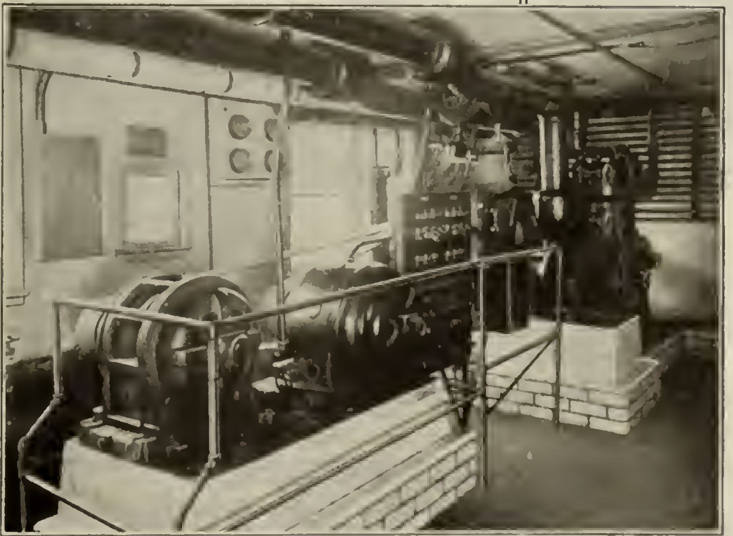
Armstrong's Mastic Finish is slightly beveled back at the edges, leaving shallow, V-shaped joints between the boards when erected. Mastic filler is flowed into these joints with a hot iron, sealing them perfectly and amalgamating with the A M F to make an unbroken finish over the entire insulation.

A sample of AMF Nonpareil Corkboard sent on request. Full information will be gladly furnished.

Armstrong Cork & Insulation Co., Ltd.,
902 McGill Bldg., Montreal, Que.; 11 Brant Street, Toronto, Ontario, Can.
Also manufacturers of Nonpareil Cork Covering for brine and ammonia lines, coolers and tanks.

NONPAREIL CORKBOARD INSULATION

For All Cold Storage Rooms



An installation of York Enclosed Refrigerating Machines in a Candy Factory.

Mechanical Refrigeration

—is an important adjunct to many lines of industry and commerce. In moderate size installations the best results can be obtained by using the—

YORK Enclosed Machine

These machines can be driven by any available power. Their simplicity of construction permits them to be operated successfully by employes, who have had no previous experience in operating one.

They are carried in stock in all our warehouses for prompt delivery. Write our nearest office and give our engineers the opportunity to assist you in solving your Refrigerating Problems.

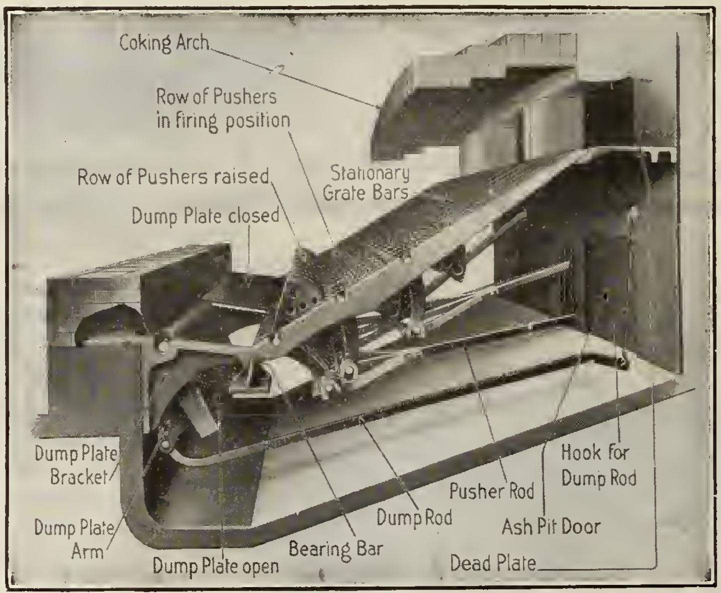
The National Hand Fired Stoker Why You Should Use It

800 tons of coal saved in six months! Such an announcement borders on the unbelievable. Yet it is the actual experience of a manufacturer who, somewhat against his will, was induced to instal the National Stoker.

During this heating season, the average outdoor temperature was 8 F. lower than that of the preceding winter. Yet the economy and efficiency realized with the National Hand Fired Stoker were so high that the plant was operated on only three boilers. Previously, four boilers had been required.

The principal advantages derived from the use of the National Stoker are saving in coal consumption, prevention of smoke with all grades of coal, increase in boiler capacity and saving of labor cost. The National Stoker ensures continuous firing and uniform conditions; a progressive distillation of volatile matter and proper provision for burning it; an even distribution of coal, and greater ease in obtaining good economy. It eliminates the loss of unburned coal with the ashes. It guarantees a clean stack which will comply with any city smoke ordinance without the use of steam jets or other devices. It offers to firemen relief from strenuous duties and from long exposure to intense heat.

With the National Stoker the heaviest labor of firing is eliminated and the number of men in the boiler room is smaller than the number required in plants with ordinary grates. Moreover, the firemen need not be skilled. Every part of the National Stoker is simple and its function can be quickly understood.



The downward sloping banks of grates operated by convenient pusher rods from the front of the furnaces, enable even "green" help to get almost perfect stoking results with almost any grade of fuel. The special Coking Arch construction, possible only with the downward slope of the fire grates, is the most successful smoke-consuming device yet developed. Visible smoke consists chiefly of very small particles of soot. Even though these particles are heated above their ignition temperature, ordinarily they burn very slowly if the air supply is insufficient, or if they are not intimately mixed with the free oxygen of the air.

In hand fired furnaces without the Arch, there is usually plenty of oxygen, but it is supplied in large streams which tend to flow through the combustion space parallel with the gases carrying the particles of soot. The oxygen may not come into contact with the particles of soot, and thus they leave the furnace and boiler setting as visible smoke. This carbon burns freely with the National.

The National Stoker abates visible smoke by effecting complete combustion with all kinds of coal—by providing a sufficient, even air supply, mixing it with the combustible gases and the particles of soot or carbon, and by maintaining a temperature high enough for the ignition of the combustible while it is mixing with the air. Thorough mixing is obtained by means of the durable fire-brick ignition arch in the combustion space and complete combustion follows:

The grates are set at a 30° incline, and allow a free and easy handling of the fuel down the grate. There is no risk of good fuel avalanching when the dumps are lowered.

Between the grates are two or three rows of long-travel fuel-pushers. Each row is independently operated by means of a lever on the boiler front. By lowering the dump plates and raising the lowest row of pushers, ash and clinker are thoroughly cleaned from the bottom of the grates without disturbing the good coal and coke on the upper part of the grates. For this reason, there is practically no unburned carbon or coke in the ash. The fire can be cleaned without losing a pound of steam pressure.

The National Stoker voids the ash without raising it into the hot zone of the fire bed, and therefore without producing clinker. This is the reason why it has proved eminently successful in handling high ash, free burning western coals. With eastern caking coals, the pushers break up the cake so air can get through, thereby making possible a high rate of driving with only moderate draft. The National Stoker keeps the fire bed clean at all times. By thus preventing smoke, the National Stoker insures proper furnace operation, and a smokeless stack. Its remarkable economy, ease of operation, and low cost are making this Stoker the choice of the more progressive manufacturers and other users of steam power up to 500 h.p.

We gladly send a fully illustrated pamphlet, explaining the National Hand Fired Stoker, on request—and entirely without obligation to you.

Diamond Soot Blowers Save Fuel at all ratings

HERE is a comparison between blowing a boiler by the hand lance method and by mechanical soot blowers. A 500 h.p. boiler is assumed, 200 lb. steam pressure, operating at 175 per cent rating, on a basis of the boiler being operated 300 days of 20 hours each per day, with an evaporation of 8 lbs.

Steam consumption is figured on the basis of each soot blower valve being open a total of 60 seconds twice a day in the case of the independent valve blower and 30 seconds in the case of the Valv-in-Head blower. Hand lance steam consumption is figured on a total flow of 20 minutes per day through a ¾" nozzle.

Operating Cost per Year with Hand Lance

Steam	$300
Labor (2 hrs. per day)	240
Maintenance	25
	$565

Operating Cost per Year with Mechanical Blowers

	Independent Valve Type	Valv-in-Head
Labor	$ 60	$ 36
Steam	184	92
Interest at 6 per cent.	40	45
Depreciation and maintenance 20 per cent.	132	148
	$416	$321
Decrease in operating cost due to mechanical blowers	$149	$244

A boiler operating under the conditions named would consume 10,500 tons of coal in a year's time. Figured at $5.50 a ton, this would amount to $57,700 per year.

2% saving in fuel would amount to $1150
4% saving in fuel would amount to $2310
6% saving in fuel would amount to $3460

From the above it will be seen that soot blowers commonly pay from 125 per cent to 800 per cent per year on the investment.

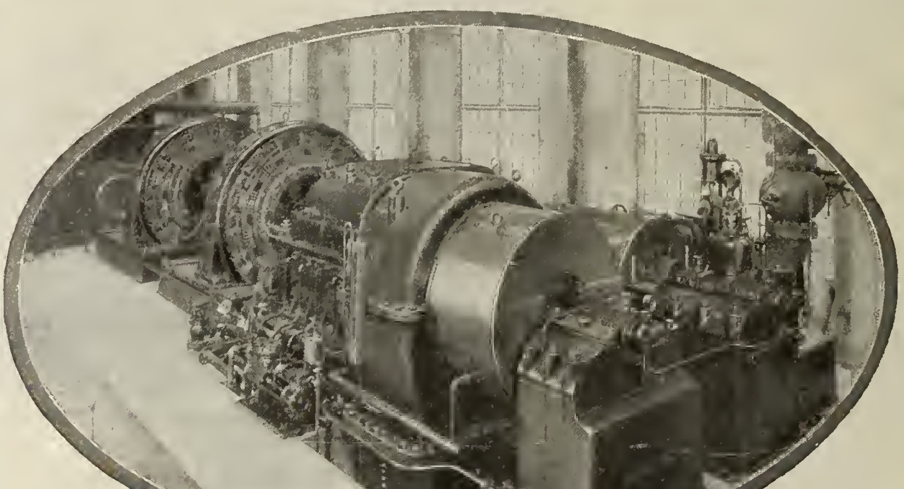
De Laval

DC Turbo Generator



THIS De Laval compound DC turbo generator at the plant of a large cement company is rated at 3,750 K.W., but will carry 4,500 K.W. for two hours without undue heating. The compound turbine with speed reducing gears, together with high superheat and high vacuum, realizes the highest thermal efficiency. The use of two turbine shafts eliminates distortion and vibration tendencies.

Industrial plants find that DC power distribution pays because it permits of each and every machine being operated at the exact speed most favorable to quantity or quality of output and it is also indispensable for cranes, elevators, blowers and other variable speed apparatus.

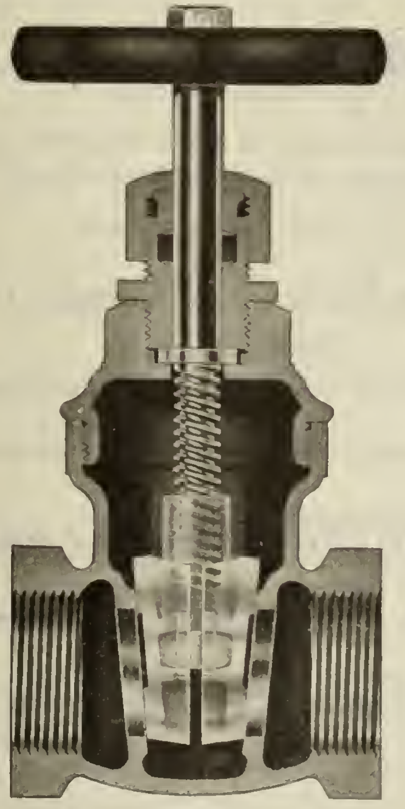
JENKINS
Type "K"
Bronze Gate Valves



Sectional View of a Jenkins Type "K" Gate Valve.

HERE'S something different from the ordinary type of Gate Valve.

Cast from virgin metal of the very highest quality and so carefully proportioned that there is no weakness at any point. Spindles are made of Manganese Bronze, and all parts are machined to gauge.

These Valves are remarkable for their reliability, their easy operation and the simplicity of their closing mechanism. Being of the split-wedge type they can be operated in any position without danger of the discs jamming.

Type "K" Valves are suitable for 125 pounds working steam pressure or 175 pounds working water pressure.

Write for free copy of Catalog No. 9 and read about these Jenkins Models in detail.

Relining furnaces? Get Plibrico here---

SOMETIMES when furnace linings are needed, they're needed quick. Then it is that the engineer is glad that Plibrico—the one-piece lining—can be had from warehouse stocks close to him, where ever he is. In Canada a 'phone call, wire or letter will start Plibrico on the way if addressed to:

Montreal—Beveridge Supply Co.
Toronto—Shell, Bar, Boico Supply Co.
Vancouver—Evans, Coleman & Evans.
Winnipeg—Winnipeg Supply & Fuel Co.
Saskatoon—Building Products & Fuel, Ltd.
Regina—Dominion Lime & Coal Co.

When you need furnace linings in a hurry order Plibrico—you'll get long life in addition to speed of delivery.

Plibrico is delivered only in steel containers of distinctive appearance, as shown above.

Greetings:

The spirit of the season prompts us to extend our thanks to our many business friends for their steady and increasing patronage.

During the year 1924 we shall endeavor to show our appreciation by giving you the best service within our power.

Best wishes for a Merry Christmas and a Happy New Year.

Compliments By Mail

THE daily mail brings many compliments but it's usually unwise to pass them along to Power House readers—well, because space is limited and compliments seem sort o' personal, to say the least of it. Here's two or three sentences, however, out of the mail the other day.

The first is from a letter by F. E. Cole, of Stratford, Ont. He says: "I certainly enjoy Power House now, and think it is the best paper on the market. I look forward to every issue and must admit it is a very great help to me in my work."

Going further—to W. Forster, in far off Winnipeg—read this: "Enclosed find a $6 money order for two subscriptions to Power House for friends of mine. I like the paper very much and hope to be able to get many more subscribers, especially after thing get a little quieter at the plant."

The last, from Fred Heinrich, of Vancouver, reads: "A salesman here has been trying to sell me some equipment I have never seen advertised in Power House. I don't know anything about it. Can you tell me if it will do what the salesman says it will do?"

Now let's look at to-day's bill of fare. While some issues may be better than others—that's largely a matter of taste—there's usually a well balanced ration in every number. Turn the pages from cover to cover and you're likely to be pleased. There are big articles and little articles; ideas that have worked and ideas that look as if they ought to work and many other interesting and worth-while things. Don't miss any of them.

* * * *

Cutting Steam Costs

IN NO direction is power plant engineering making more progress than in improvements in the use and design of steam boilers. For many years the world "tolerated" boilers as they were, occasionally it is true bringing out new designs, but making little effort to increase efficiencies or lower operating costs. Then a movement toward a more scientific attitude took place; the CO_2 recorder, and kindred devices, were introduced, and experts began telling boiler users that they were obtaining ridiculously low efficiencies.

As a rule such accusations fell on deaf ears for the engineers of those days were quite satisfied that they knew all it was necessary to know about boilers, and they laughed at the "trimmings" which the new school of thought wanted them to install in their boiler rooms.

There was some excuse for this attitude. Coal was cheap. Labor cost little more than half of what it does to-day, and the burdens of a sales tax had not to be met. Hence it came about that a few extra tons of coal a day did not matter very much, and boiler users preferred to carry on as they were rather than incur further capital charges by purchasing new equipment.

There were, of course, exceptions, but taking boiler rooms as a whole, the evidence seems to indicate that the average thermal efficiency was much less than 50 per cent. Then came the World War and a scarcity of fuel, with an increase in the cost of everything connected with steam generation on the one hand, and the necessity of reducing costs on the other, resulting in greater attention being given to the production of steam and to the improvement of boilers themselves.

Of recent developments the most notable is the coming of higher pressures, but not less important is the potentialities of low temperature distillation in the conservation of fuel. In this connection it is hoped in the December 20 issue of Power House to give readers V. Z. Caracristi's story of Henry Ford's attempts to "burn coal twice" at Walkerville.

* * * *

Coal a Source of Wealth

COAL, besides being energy in material and bulky form, is also the source of innumerable mineral products. More than one thousand coal products as vital to the Dominion as fuel itself are to-day in use. The full utilization of the whole range of values, including energy, to-day still transported in the form of coal, imposes itself in the near future.

This utilization, at present confined to the coke and gas industry whch can still be described by the term "by-product" production as it takes only half the field, must ultimately broaden itself, and become an economic force covered by the term "multiple production."

The reason for the use of the term "multiple production" at once becomes apparent when it is remembered that one ton of bituminous coal gives on an average 10,000 cubic feet of illuminating gas, 20 pounds of ammonium sulphate, 2½ gallons of benzol and 8½ gallons of tar, which represent only the primary products, while other chemicals, drugs and dyestuffs could be extracted.

If the price of one ton of coal at the mine is $1.52, the multiple products of the same ton of coal have a collective value of at least $16.

The illuminating gas and the benzoal are, the one a perfect fuel, the other an equivalent of gasoline as a motor fuel. Multiple production would make both gas and benzol important sources of power. Moreover, with the advent of industrial alcohol as fuel it must not be forgotten that gasoline is not miscible with alcohol, while it can be mixed with benzol and such mixture of gasoline and benzol can be mixed with alcohol, offering an excellent fuel for internal combustion engines.

Furthermore, ammonium sulphate has great value both as an artificial fertilizer and as a source for the extraction of ammonia, serviceable for medicinal, refrigerating and other purposes. Tar, is not only a road building and waterproofing material, but primarily is the basis of the great coal tar industry that gave Germany its industrial supremacy at the beginning of the World War.

Though the application of electricity has made great headway in the present decade, multiple production has not yet been considered for general adoption, its importance not yet having been grasped. Yet both are molding the future industrial order and as economic forces are bound to cause revision in popularly accepted ideas of economics.

Combustion Problems of Canadian Power Plants

*By THOMAS A. MARSH

Selection of Proper Fuel and Stokers, Setting of Boilers at Liberal Heights and Rigid Application of the Gospel of "Clean and Tight" Dominant Factors in Producing Cheaper Steam

THE basic problem that confronts all power producers is "How to produce cheaper steam." Cheap power or steam is a term too often only partially comprehended. Some engineers casually analyze steam costs on the basis of fuel costs per thousand pounds of water evaporated; others add firing labor and maintenance, but few indeed consider the complete and ultimate cost involving items of fuel charges; labor charges; investment charges (interest-depreciation-obsolescence); maintenance and outage charges. charges.

The solution of the problem is, of course, to have the sum of those items of cost at a minimum per unit of output, be it KWH, per ton of metal or per pair of shoes.

The problems as applied to coal burning are: The selection of fuel; the selection of stoking equipment; the design of the furnace; the operation of the plant.

Selection of Fuel

In analyzing a new power plant problem, or in selecting fuel for an existing plant, the item of selection of fuel is extremely important. Sometimes the coal cheapest in first cost makes the cheapest steam, frequently it does not. The same is true of the most expensive coal. So far as apparent steam costs are concerned, it is a simple matter to analyze coals of any heat content. Fig. 1 indicates such an analysis. This is one important consideration in coal selection. Other important items bearing on fuel selection are:

- Ability to carry the plant load;
- Reliability of supply;
- Mine equipment;
- Mine preparation;
- Ability of producer to give uniform quality;
- Transportation facilities;
- Adaptability to stoking equipment (installed or contemplated);
- Service (engineering assistance);
- Storage properties of coal;
- Boiler capacity obtainable;
- Maintenance of furnaces and stokers;
- Labor of firing;
- Responsiveness to meet sudden load demands;
- Smokelessness;
- Cost of ash removal.

The reason for each of these items is so obvious that discussion is unnecessary, but it is well to keep the entire list before us in selecting fuel lest we overlook one or more to the detriment of ultimate costs of steam.

In Canada there are coals of almost all descriptions, from lignite to high-grade bituminous. These coals have various characteristics. Fig. 2 indicates the general coal classification and approximate analysis. To some, this appears a complex problem, but when we change the chemical terms of H_2O, vol., fixed carbon and ash to the simpler terms of water, tar, coke and dirt, the problem is within the grasp of every man.

Composition of Coal

Coal is composed of just these four constituents. Whether a coal is a lignite or anthracite is largely one of water and tar content. Bituminous coal means tarry coal (30 to 40%). Semi-bituminous means half tarry (15 to 20%). Tar tends to make smoke, therefore the bituminous coals are the smoke coals and require special furnace design to permit the burning of the tars in the furnace, and, on the other hand, the semi-bituminous coals are smokeless coals. Anthracite, or hard coal, has practically no tar and is smokeless.

Some coals are high in ash and some low. About 10% is commonly considered a dividing point on this item. Some are very high in ash as, for instance, Iowa coal with 30 to 40% of ash. Such coal is inert and unresponsive in the ordinary furnace, and, due to the large percentage of non-combustible (52%), requires very liberal grate areas and long arch construction to produce reasonable ratings.

Of other fuels, the lignites are high in moisture and present a problem of their own. This problem has been partially met by the stoker, but much remains to be done. There are limits to combustion rates and quality of coal which should be extended. Excellent results have been obtained with Soruis and Drumheller by the use of liberal grate areas, long arches and vertical reflecting bridgewalls, but there must be greater possibilities by means of air control, preheated air, powdered fuel and low temperature distillation. Much has been done and there are many successful installations using these fuels, but the art of burning coal is in its infancy and much development may be expected.

Analysis Means Little

The analysis of coals given above really indicated little. What we are really interested in regarding a fuel is:

- Storing qualities.
- Firing characteristics:
  - Slow or responsive;
  - Burn to clean ash or retain coke;
  - High or low ash;
  - Clinkering or non clinkering;
  - Smoky or smokeless (relative only).

These are practical considerations known to the operating engineer of every plant and considerations which should be given weight.

Dissimilar as are the coals listed above in Fig. 2, both in chemical analysis and in firing characteristics, it must be evident that no one stoker or furnace is suitable to all.

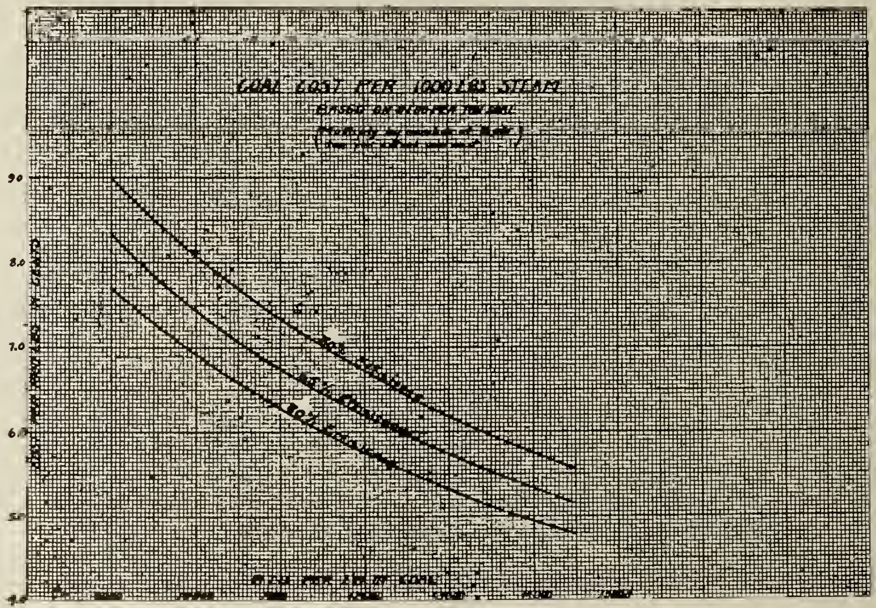

Fig. 1.

---

*Chief Engineer, Green Engineering Co. Contributed to Power House through the courtesy of A. J. Taylor, president, Combustion Engineering Company, Toronto.

The grate areas necessary for lignite would be excessive for a good grade of bituminous or semi-bituminous coal.

The arches and brickwork required to build up furnace temperatures with lignite would present an impossible maintenance problem with high-grade coals.

The furnaces used with high-grade coals cannot be successfully operated with lignite or 30% ash coal.

Pulverized coal perhaps should be considered as an exception to this consideration, as coals of dissimilar characteristics act quite similar in a pulverized fuel furnace.

Recognizing the inadequacy of any one stoker to burn all coals, the trend in the stoker industry has been toward combinations of equipment under one organization in order to be able to treat each problem in an unbiased manner and in order to make available the best engineering experience.

This is unquestionably a logical development and one advantageous to both customer and manufacturer and leads into a discussion of stokers:

Designed in 1785

The earliest mechanical stoker for steam boilers was probably designed by James Watt in the year 1785. The mechanism was simply a device to push the coal, after it was coked at the front of the grate, back toward the bridgewall. The suggestion of Watt was followed by numerous patents in Europe for mechanical stokers, but none of these have been adopted to any considerable extent because of their supposed lack of adaptability to boiler practice on this continent. Their non-adoption here was partly due to lack of knowledge of the art.

Another objection was that, in many cases, the grates were so placed as to be almost inaccessible either for examination or altering the condition of the fire by hand, or for renewing worn out parts.

In the early stages, stokers were exceedingly unmechanical, having parts not readily renewable, exposed to the heat with very poor mechanism for driving and adjusting. This, with the little knowledge then existing as to draft requirements, coal characteristics and furnace design, made early installations of limited performance, and resulted in numerous failures.

Much has been written of the early history of combustion and stokers. The items affecting our present coal consumption and the economy of existing plants are the types of stokers and furnaces used during the last twenty years. Few older plants are in service to-day and therefore do not affect our problem.

At the beginning of the century, many plants were installed which are in service to-day, sometimes advisedly, but frequently inadvisedly; however, they are in operation and are a factor in our fuel consumption.

Four Types of Stokers

At that time there were four types of stokers—the front inclined stoker, the side inclined stoker, the chain and traveling grate, the underfeed.

In general, large central stations in the United States using coals other than anthracite, used inclined or underfeed stokers. In the Pittsburgh district, the field was divided between the inclined type and the chain grate. In the west, all types had a share, with the chain grate predominating.

Forced draft was used only with the underfeed stokers, although in one or two isolated cases attempts were made to house in inclined overfeeds and chain grate stokers and put them under pressure.

Such results were unsatisfactory, as there was no adequate control of the fuel bed in conjunction with air pressure.

At the beginning of the century, most plants operated at from 100 to 125% rating, and 150% rating was rare indeed. In 1910 the demand for steam had increased and 150% rating was the average rating with 175 to 200 in the occasional plant. By 1915, 200% was common and 250% was reached in some plants.

By 1920, ratings had reached 300%, with some plants reaching 400% on peaks, and the end is not yet with superstation stokers and pulverized fuel.

Until 1910, the majority of plants used natural draft. About that time the multiple retort underfeed stoker entered the field and ratings of 250 and 300% were soon reached.

During the ensuing ten years, the multiple retort underfeed stoker was developed by several companies and unusually good results were obtained with Eastern coals, as high ratings could be reached with excellent efficiency and low banking losses. Maintenance in general was low and the net results were lower steam costs and increased capacity.

The successes of this type of stoker in the East caused Western engineers to attempt similar installation in the West. These were in general not so satisfactory, as the Western coal clinkered more readily, sometimes necessitating a discrimination between coals, resulting in the more costly coal being selected and increasing the cost of steam power.

TABLE OF CONSTITUENTS OF COAL

	% H_2O	% Vol.	% Fixed Carbon	% Ash	B.t.u. per lb.
Anthracite	2.8	1.2	88.2	7.8	13,300
Semi-Anthracite	2.0	6.6	58.2	33.2	9,700
Semi-Bituminous	4.6	13.5	76.7	5.2	14,400
Eastern Bituminous	8.6	32.4	51.3	7.7	12,200
Western Bituminous	10.1	33.2	42.0	15.7	12,000
Iowa High Ash Bit.	20.2	27.9	20.7	31.2	7,499
Sbu. Bituminous	22.4	41.2	32.2	4.2	6,100
Lignite	34.4	25.9	30.9	8.8	7,200

Figure 2

Application of Draft

The development then led to the application of the forced draft traveling grate with compartments or air zones to Western fuels. This stoker was designed and developed in the anthracite fields for the burning of small sizes of anthracite. Later it was found that it would burn coke braize, which opened another field. The stoker was a success from the start with Western high ash fuels, and is the standard at present in the high ash field.

About this time, the single retort underfeed with side grate bars was developed and has found a wide application with coals having any tendency to coke, coals severe in maintenance of grate bars and in installations limited as to ash pits. This stoker, to quite an extent, commercially replaces the older inclined overfeed natural draft types of the previous decade.

These are the general stoker types, selection of which must be made with a thorough knowledge of the fuel situation. Underfeed stokers handle coking coals satisfactorily. Clinkering high ash coals are best burned on traveling grates with forced or natural draft, as the load may demand. Usually, however, the coal market, load and physical conditions make the problem pretty clear cut.

Pulverized coal burning has made progress during the last twelve months. A good percentage of the central stations in the United States are adopting this firing system. Almost every power station design to-day involves a careful analysis of stokers as compared to pulverized coal, with a rapidly increasing number decided in favor of the latter.

The higher combustion efficiencies of pulverized coal and its ability to handle all coals is seldom questioned. The figures that must be considered are investment and preparation costs. Modern designs and improved equipment, however, are continually increasing the field, so it seems evident that more and more installations will be seen.

Expect Better Designs

As always in history, the entrance of a new competitor in the field has stimulated better efforts from the existing contenders, so daily we may expect improved stoker and furnace designs. This actually is going on to-day. The competition between these two firing methods will be most interesting during the ensuing years, but it should be realized that there will always be a field for pulverized coal and a field for stokers. Sometimes the line is distinct, sometimes indistinct. Developments of each equipment will vary the limits of adaptability.

In the future, we may consider each of the present-day methods as crude. Engineers here and abroad are working feverishly on low temperature distillation processes and many experimental installations are to-day under construction or contemplated.

The application of such systems would at once solve our problems of low-grade fuel utilization, domestic and industrial fuel, transportation (if located at mines), and give a supply of valuable by-products in addition.

Design of the Furnace

The furnace is the chamber between the grate which supports the fuel and the boiler which absorbs the heat. In the furnace, combustion should be completed. The size of furnaces and their shapes depend on the characteristics of the stoker, the coal and the rating. Furnace design requires experience and knowledge of the problems involved, both theoretical and practical, and should be entrusted to the best talent available.

Furnace design has been an evolution. The old low-set boilers of ten and fifteen years ago are no longer approved, but have been superseded with furnaces of liberal design.

As to furnace size, the Stoker Manufacturers' Association have agreed on minimum heights at which boilers should be set. These are shown in Fig. No. 3. No new boiler should be set at lower heights, and more is preferable considering the problem in its elements.

A pound of coal is a cube three inches on a side. It must combine with a cube of air six feet on a side. This states the problem in units we can all grasp. True, the problem is not all one of volume. Effective volume and the time element enter strongly into the calculation for the completion of the reactions of combustion from the above basis. However, you can readily appreciate the need for liberal areas of air and gas passages and of liberal furnaces for a reaction involving such volumes. Consider also the high volatile coal (30 to 40%). Substantially all of this must be burned in the furnace without flame actually passing into the boiler heating surface if anything approaching smokelessness is to be obtained.

A Rule of Thumb

As to a unit for furnace volume, a rule of thumb has been during the past few years: "Two cubic feet of furnace per horsepower developed." This is not specific and does not provide for variations in fuel. A better basis is B.t.u. liberated per cubic feet of furnace per hour.

Stoker furnaces have been designed on the basis of 18,000 to 24,000 B.t.u. liberated per cubic foot of furnace per hour. Just how large to make the furnace depends on the load factor at which it will be operated.

The design should be made to meet the average conditions with some sacrifice for occasional peaks.

Operation of the Plant

With an engine turbine or almost any other equipment in the power plant other than stokers, the efficiency is "built in" to the design at the factory. With stokers and furnaces this is only partially the case. One operator can, with certain stokers, obtain 75% efficiency. while a less able or careless operator will obtain 55 or 60% with the same equipment. This is one argument for pulverized coal.

Considered basically, we are dealing with two fundamentals, namely, pressure, either of air, water or steam, and heat transfer, through either steel, water, masonry or other parts. Pressure can only be maintained by tightness. Heat transmission is dependent on cleanliness.

We must not belittle the talent required to keep a power plant clean and tight. To do so requires not only knowledge of what to keep clean and tight—how to do it—but how to maintain it so. The problem resolves itself to one of knowledge, experience, organization and application, just as any other real proposition.

SETTING HEIGHTS FOR VARIOUS TYPES OF BOILERS EQUIPPED WITH STOKERS

(Min. = absolute minimum; P.M. = preferred minimum, i.e., the minimum heights recommended.)

TYPE OF BOILER	TYPE OF STOKER TO BE INSTALLED

Fig. 3.

The application of these words in the power plant requires, so far as the fuel is concerned: clean fuel free from dirt; clean ash pits; clean furnaces free from slag formations; clean boilers, no soot; clean breeching, no undue soot accumulations; clean stacks; tight fires, no air holes; tight ash pits, no air leakages; tight furnaces, no air leakage; tight boiler settings, no air infiltrations; tight baffles, no short circuits; tight breeching, no air leaks; tight stack, no air leaks.

In the water circulation the words apply to: clean water; clean pumps; clean lines and valves; clean boilers, no scale or sediment; tight pumps; tight lines and valves; tight boilers; tight blowoffs in other valves; tight steam lines.

In addition to the items specifically mentioned, there are many other little nooks and corners to look for the application of the words "clean and tight."

In general, the entire boiler room should be kept CLEAN. Cleanliness in general has much to do with operating economy. Piles of rubbish—waste material and dirt—around a boiler room almost invariably indicate a similar condition inside boilers and other parts of the system.

Is It Clean and Tight?

If the operating engineer will consider every point throughout the entire path of the coal, the air, the water, and the steam, and apply the two questions, "Is it clean?" and "Is it tight?" and not be satisfied until he can answer positively, that power plant will show economy far above the average.

It is not necessary in most stations to consider redesign of equipment. It is the function of expert furnace designers to decide whether furnaces should be changed, boilers raised, and other physical changes made to the plant.

It is the function of the engineer to determine whether new boilers, economizers, stokers or other equipment should be installed, but it is also his function to produce results with the existing plant and equipment.

The engineer who has learned the meaning and application of these two words, and can maintain his equipment "clean and tight," is the engineer who will make the record for high economy.

In conclusion, it is to be hoped every Canadian engineer will bear in mind the four items:

1. Select fuel based on all items involved.

2. Select stokers that will make cheapest ultimate steam.

3. Set boilers at liberal heights to permit ample furnace designs.

4. Get religion on the gospel of "Clean and Tight" as applied to operation.

Operating the Steam Engine in the Power Plant

*By CHARLES L. HUBBARD

Gains in Economy by Using a Condenser Depend Upon Degree of Vacuum Maintained and the Mean Effective Pressure of the Engine When Running Non-Condensing

THE interests of the plant owner and superintendent, as regards the steam engine, are essentially different from those of the designing or mechanical engineer, although based on the same underlying principles.

The owner is chiefly concerned with matters relating to types, selections, and operation, while details of construction, except in a general way, are best left to the judgment and experience of the designing engineer.

These principles, while elementary to the engineer, are not always fresh in the minds of those in charge of a plant, and furthermore, as being practical application has an important bearing upon matters with which they are intimately connected, it seems best to devote a limited amount of space to going over these principles briefly before considering the selection and operation of engines.

Explanation of Terms

In dealing with steam apparatus we are constantly coming in contact with the term "pressure," expressed in a variety of ways, as absolute pressure, gauge pressure, vacuum, inches of mercury or water, barometric pressure, and so on. In order to understand clearly what follows, these terms should be well fixed in the mind of the reader.

Absolute pressure, as the name indicates, starts from zero or no pressure. Gauge pressure means a pressure above that of the atmosphere, and starts at 15 pounds per square inch (14.7 pounds accurately) absolute. For example, gage pressure plus 15, equals absolute pressure, and absolute pressure minus 15, equals gage pressure.

A vacuum, as used in engineering work, means any pressure below that of the atmosphere, and is commonly expressed in inches of mercury. A column of mercury having a sectional area of one square inch, and a height of one inch, weighs very nearly 0.5 pound, so that when placed in a U-tube, as in Figure 1, the balance column "H" represents a pressure of 0.5 pound for each inch in height. If in Figure 1, H=10 inches, and the right leg of the U-tube is open to the atmosphere, the absolute pressure in chamber "A" will be $15+\frac{10}{2}=20$ pounds per square inch. To change inches of mercury to pounds pressure per square inch, divide by two. To change pounds per square inch to inches of mercury multiply by two.

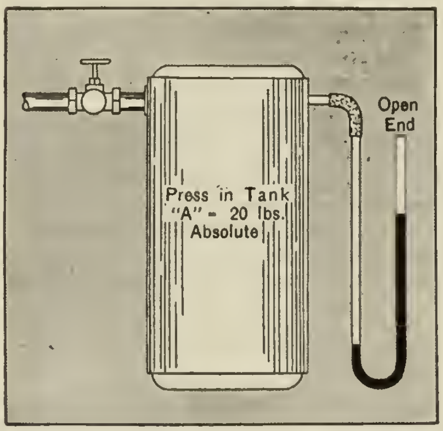

Figure 1: A vacuum is commonly expressed in inches of mercury, the difference in height between the two levels of mercury in a U-tube.

Atmospheric Pressure

The atmospheric pressure is very nearly 15 pounds per square inch absolute, (zero gage pressure) which corresponds to 15×2=30 inches of mercury.

Barometric pressure is the absolute atmospheric pressure expressed in inches of mercury, as above, and may be taken as 30 for ordinary power plant purposes.

The pressure in a condenser is commonly spoken of as so many inches of vacuum. For example, a condenser pressure of 26 inches of vacuum means that the pressure within the condensing chamber is less than that of the atmosphere, by an amount measured by 26 inches of mercury column. That is, the condenser pressure is 30—26—4 inches of mercury, or=2 pounds per square inch, absolute.

Now as to the meaning of the terms "work" and "power" and the relation between them. A force or pressure active through space produces work. The unit of work is the foot-pound, and is the work done in raising a weight of one pound, one foot in height. A force of one pound acting in any direction, through one foot of space, produces the same amount of work.

Rate of Doing Work

Power is the rate of doing work, or the amount done in a specific time. The unit of power is the horse-power, which is equivalent to 33,000 foot-pounds per minute. As work may be transformed into heat, in the ratio of 778 foot-pounds

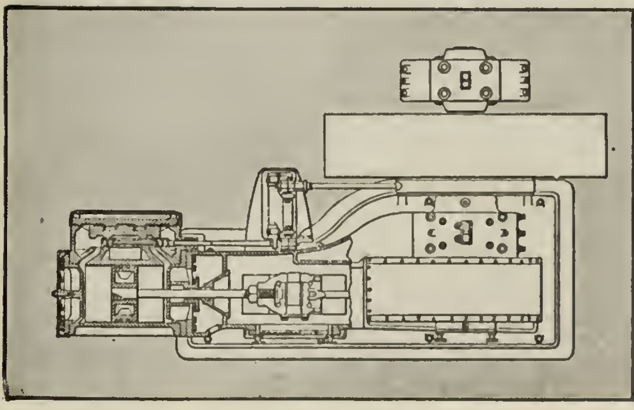

Figure 2: The essential features consist of a closed cylinder fitted with a piston and rod, and a valve so arranged as alternately to admit and exhaust steam.

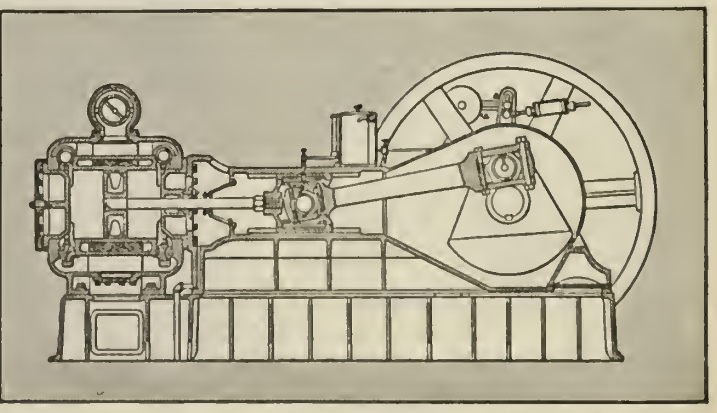

Figure 3: In the four-valve engine four separate valves, as the name implies, take care of inlet and exhaust; two for each end of the cylinder.

---

*Consulting engineer on power house problems. Reprinted in Canada by special permission from Factory, the Magazine of Management.

per B.t.u. and vice versa, it follows that one horse-power represents the equivalent of $\frac{33{,}000\times 60}{778}=2{,}546$ B.t.u. per hour.

The steam engine converts heat into work and steam is the medium for transferring the heat from the boiler furnace to the engine. The essential features of an engine are very simple, and consist of a closed cylinder fitted with a piston and rod, and a valve so arranged as alternately to admit and exhaust steam from each end of the cylinder. In operation, high-pressure steam is admitted to one end of the cylinder until it is partially filled. The valve then closes, and the piston which has been pushed forward by the pressure of the steam back of it, continues to move to the end of its stroke, due to the force exerted by the expansion of the steam which was trapped in the cylinder at the closing of the valve.

Belt Takes Power

During the forward stroke of the piston the low-pressure steam in front of it is forced out through the exhaust valve into the atmosphere or condenser. At the end of the stroke the admission and exhaust valves are reversed, and the operation is repeated on the return stroke. The reciprocating motion of the piston is made to give a rotary movement to a shaft and fly-wheel, from which the power thus generated is taken off by a belt, gearing, or other means.

The general construction of a simple slide-valve engine is shown in Figure 2, and requires no description for the power plant engineer.

In case of an engine exhausting into the atmosphere, there is a back pressure of 15 pounds per square inch, plus the frictional resistance of the exhaust pipe which amounts to the equivalent of about two pounds per square inch in the average case, making a total of approximately 17 pounds absolute. The back pressure is constant throughout the stroke, from the opening to the closing of the exhaust valves, while the forward pressure varies, constantly falling from the time the admission valves are closed (cut-off) until the end of the stroke, due to the expansion of the steam. The actual working force acting on the piston at any point during the stroke is called the effective pressure. It is evidently the difference between the forward pressure, and the back pressure at that particular point.

Table I

Cut-off	Percentage of Clearance							
	1	2	3	4	5	6	7	8
1-10	.344	.357	.369	.381	.392	.403	.413	.423
1-8	.397	.408	.419	.429	.439	.448	.457	.466
1-6	.475	.484	.493	.502	.510	.517	.524	.531
1-4	.603	.609	.615	.621	.626	.631	.636	.641
1-3	.704	.708	.712	.716	.720	.724	.728	.731

The work in foot-pounds done per stroke of the piston, is equal to the average or mean effective pressure in pounds, acting throughout the stroke, multiplied by the length of stroke, in feet.

Mean Effective Pressure

Neglecting the cylinder losses, (condensation, radiation, leakage, and so on) the mean effective pressure may be computed from the initial or boiler pressure when the point of cut-off and clearance (waste or dead space in cylinder at end of stroke) of the engine are known by means of Table I and the formula $P=(p\times f)-b$, in which

P=mean effective pressure, in pounds per square inch.

p=initial pressure, in pounds per square inch, absolute.

f=factor from Table I for the given cut-off from clearance.

b=the absolute back pressure,=about 17 pounds per square inch for non-condensing engines, and 3 pounds in the case of condensing engines.

As an example, to find the mean effective pressure (m.e.p.) for an engine having a clearance of 5 per cent. cutting off at one-fourth stroke, supplied with steam at 80 pounds gage pressure (95 pounds absolute) and exhausting into the atmosphere against a frictional resistance equivalent to two pounds per square inch (17 pounds absolute), we would proceed as follows:

Substituting in the formula, we have $P=(95\times 0.626)-17=42$ pounds.

The actual pressure will be somewhat less than this, due to the various cylinder losses, "wire-drawing" through the steam passages, and so on, depending upon the type and speed of engine. For an accurate determination of the m.e.p. a diagram must be taken with a steam engine indicator, but for approximate work the result computed by the formula may be corrected by the following factors for different types of engines:

Table II

Type of Engine	Factor
Simple high-speed	0.70
Simple medium-speed	0.85
Simple slow-speed	0.90
Compound high-speed	0.65
Compound medium-speed	0.80
Compound slow-speed	0.85

In case the engine in the above example was of the simple medium-speed type, the m.e.p. would be very close to $42\times 0.85=36$ pounds.

The horse power of an engine is given by the formula:

$$H.P.=\frac{P\times L\times A\times N}{33{,}000}$$

in which

H.P.=horse-power of engine.

P=m.e.p. in pounds per square inch.

L=Length of stroke in feet.

A=area of piston, in square inches.

N=Number of strokes per minute,= revolutions of shaft×2.

Suppose in the case already referred to, the engine had a cylinder 14 inches in diameter, an 18-inch stroke, and made 200 revolutions per minute, what would be the horse-power? Here we have:

P=36

L=1.5

A=154

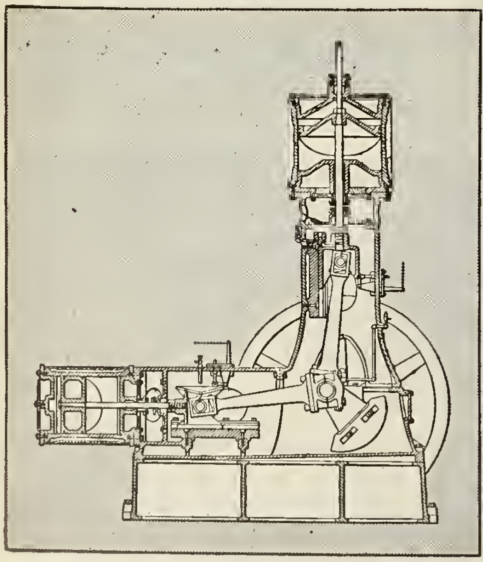

Figure 4: By compounding engines there is a 10 to 15% gain in economy. Placing the cylinders at an angle saves space.

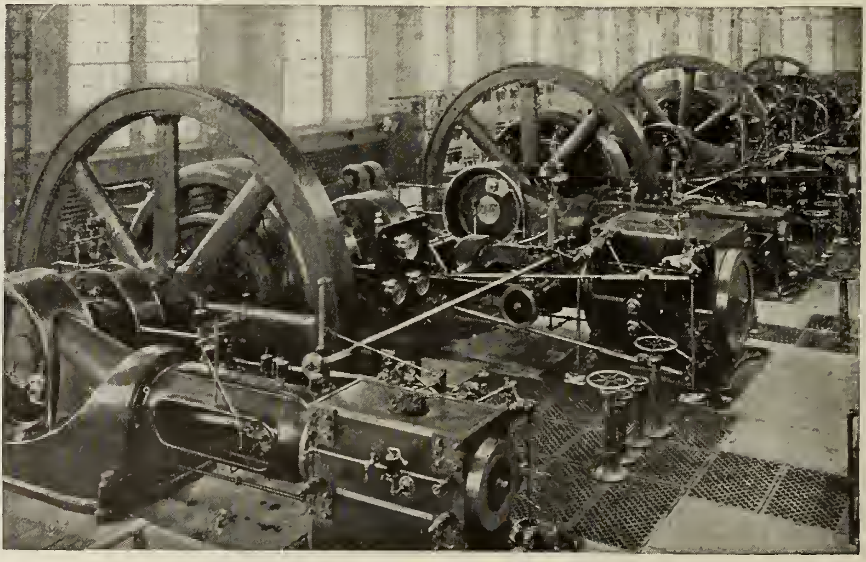

Figure 5: Cross compound engines are really two separate engines, except that they use the same main-shaft and fly-wheel. This type requires more floor space than does the angle or the tandem compound engine.

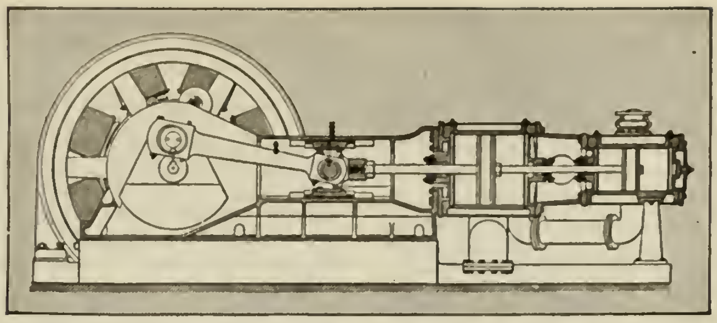

Figure 7: Tandem compound engines have two cylinders arranged in tandem, as the name implies. All other parts of the engine are used in common.

N=400

$$\text{or H.P.}=\frac{36\times1.5\times154\times400}{33{,}000}=100$$

Now let us consider engine efficiency. The efficiency of an engine is expressed in two ways, the mechanical efficiency and the thermal efficiency. The power of an engine computed by the method just given or from an indicator diagram is called the indicated horse-power, and includes the work or power required to overcome the friction of the engine itself. The delivered or brake horse-power is the power actually delivered by the engine shaft, and is equal to the indicated horse-power less the power required to drive the engine, considered as an independent machine.

Brake Horse Power

The brake horse-power of small-and medium-size engines is measured directly by means of a pony brake or dynamometer. (See Figure 8.) In case of very large machines, the indicated horse-power is computed from indicator cards taken with the engine running free, without load. This gives the power required to drive the engine alone, and is commonly called the "friction load." The brake horse-power in this case is found by first computing the indicated horse-power at full load, and subtracting the friction load.

The ratio of the brake horse-power (b.h.p.) to the indicated horse-power (i.h.p.) is called the mechanical efficiency, and commonly runs from 85 to 95 per cent. at normal or full load. For engines of the type and size commonly employed in industrial plants 92 per cent. may be taken as a fair average for approximate work. As the frictional horse-power is fairly constant for all loads, the machine or mechanical efficiency for the underloads is necessarily much less.

In determining the power of an engine for a plant operated on a system of electrical transmission, which is quite generally used in new construction, it is necessary to consider not only the machine efficiency of the engines but of the generators and motors as well. Generator efficiencies vary from 90 to 97 per cent. at rated load, tending to rise with the size of unit. For preliminary calculations a value of 94 per cent. may be used.

Motor Efficiencies

Motor efficiencies vary widely with the size and load, and may be taken approximately as follows:

Table III

Motor Efficiencies

Efficiency at Different Loads

H.P. of Motor	50%	75%	100%	130%
1	0.51	0.54	0.55	0.52
2	0.61	0.64	0.65	0.62
5	0.70	0.74	0.75	0.72
10	0.74	0.77	0.78	0.87
50	0.83	0.87	0.88	0.90
75	0.86	0.89	0.90	0.90
100	0.88	0.91	0.91	0.91
150	0.90	0.92	0.92	0.91
200	0.91	0.93	0.93	0.91

The combined efficiency of a system of power generation, transmission and transformation, is the product of the various efficiencies used in the system.

For example, the indicated horse-power of an engine for delivery of 500 brake horsepower through ten 50 h.p. motors,

$$\text{should be}\ \frac{500}{0.92\times0.94\times0.88}=658\ \text{i.h.p.}$$

The thermal efficiency of an engine or turbine is the ratio of the heat converted into useful work to that supplied, measured above the heat in the liquid at exhaust pressure. This is equal to:

$$\frac{2{,}546}{W\ (H\text{-}q)}$$

in which

2,546=the heat equivalent of one horse-power, in B.t.u. per hour.

W=pounds of steam required per b.h.p. per hour.

H=heat in one pound of steam at initial pressure=(latent heat of vaporization×quality of steam)+heat in the liquid.

q=heat in the liquid at exhaust pressure.

Example—To find the thermal efficiency of an engine operating under the following conditions:

Initial steam pressure (gage)	130 lbs.
Quality of steam	97%
Exhaust pressure (gage)	2 lbs.
Steam per b.h.p. per hour	30 lbs.

we proceed as follows:

From a Steam Table we find:

Latent heat at 130 pounds pressure	=865 B.t.u.
Heat in the liquid at 130 pounds pressure	=327 B.t.u.
Heat in the liquid at 2 pounds pressure	=187 B.t.u.

Hence H=(865×0.97)+327=1,166 B.t.u.

Substituting the above values in the formula gives an efficiency of $\frac{2\,546}{30\ (1{,}166-187}$ =0.0867 of 8.67%, which means that only 8.67% of the heat contained in the steam supplied to the engine is employed in doing useful work. Most of the remaining passes out with the exhaust in the form of low-pressure steam and water, while a small amount is lost by radiation from the engine cylinder and adjacent parts. The actual efficiency will, of course, vary in different cases, depending upon the size and type of engine conditions under which it is operated.

When W is given in pounds of steam per kilowatt hour, as is often the case where electric transmission is employed, the formula becomes:

$$\text{Efficiency}=\frac{3.413}{W\ (H-q)}$$

In case of superheated steam, the value of H may be taken directly from a table giving the properties of superheated steam, or may be computed from

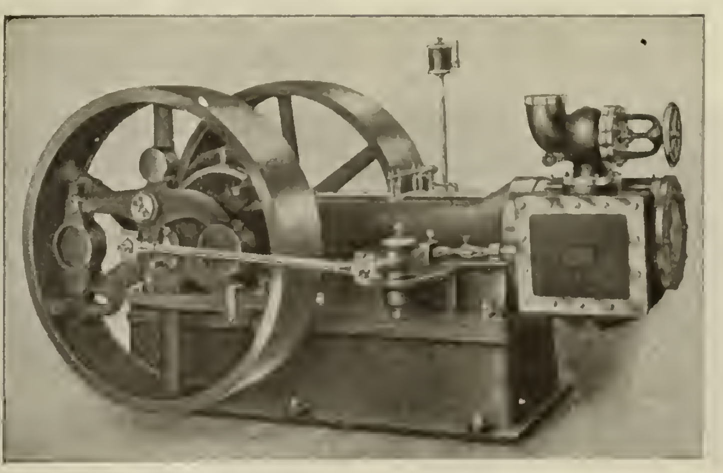

Figure 6: "Automatic engines" have a governing device consisting of two weights attached to a pivoted lever in the fly-wheel. As the weights fly outward cut-off is shortened

saturated steam by the methods given in a previous article.

Operating Economy

The operating economy of a steam engine is commonly given in pounds of steam per i.h.p. per hour, although in electrical work it is often expressed in pounds per k.w. per hour, as noted above. The power developed per unit weight of steam supplied varies with the initial pressure, ratio of expansion, type and size of machine, and its general condition.

The following table gives the approximate water-rates for non-condensing simple engines of different types supplied with steam at 100 pounds pressure.

When the water-rate per brake horsepower is required, it may be obtained approximately by dividing the figures in the table of steam consumption given below by 0.92.

Table IV

Pounds of Steam per i.h.p. per Hour
Type of Engine

I.H.P. of Engine	Single-Valve, Throttling	Single-Valve, Automatic	Four-Valve, Automatic	Corliss
40	42 to 46	33 to 36		
60	39 to 43	30 to 33	26 to 28	
80	38 to 42	29 to 32	25 to 27	25 to 27
100	38 to 42	28 to 31	25 to 27	25 to 27
150	37 to 41	28 to 31	25 to 27	25 to 27
200	37 to 41	28 to 31	24 to 26	24 to 26
250	37 to 41	28 to 31	24 to 26	24 to 26
300	37 to 41	28 to 31	24 to 26	24 to 26
400	37 to 41	28 to 31	23 to 25	23 to 25
500	37 to 41	28 to 31	23 to 24	23 to 24

Valves and governing devices will be touched upon briefly in a following article in Power House, but it may be as well at this point to distinguish between throttling and automatic engines, as these terms appear in Table IV. In throttling engines speed regulation is secured by throttling the supply pipe at the cylinder, thus reducing the initial pressure when less speed is required, and vice versa.

Varies Quantity of Steam

In case of the automatic engine, speed regulation is obtained by means of a governing device attached to the admission valves which changes the point of cut-off and thus varies the quantity of steam admitted to the cylinder per stroke.

It will be noted from the table that automatic engines are considerably more economical in the use of steam. The governing device of an engine of this type is shown in Fig. 6, and consists of two weights attached to a pivoted lever in the fly-wheel. When the speed reaches a given maximum, centrifugal force throws the weights outward, against the tension of the spring, thus swinging the arm a small distance on its pivot and so reducing the throw of the valve rod by suitable levers, and shortening the cut-off.

Mention has already been made of the loss resulting from cylinder condensation. The most effective method of reducing this is by compounding, that is, expanding the steam in two cylinders instead of one. The same process is also carried out in three cylinders in some cases, but the triple expansion engine is rarely used at the present time owing to the excessive cost of construction. Furthermore, the high rate of expansion, and reduction in cylinder condensation, which may be realized both in the uniflow engine and steam turbine make it possible to secure efficient results without the expense involved in the building of multiple expansion engines.

Surplus of Exhaust

Compound engines are still employed in plants where there is a surplus of exhaust which cannot be utilized and it is, therefore, desirable to secure as low a water-rate as possible.

If a given weight of steam is expanded through the same range of temperature in two cylinders, one exhausting into the other, instead of in a single cylinder, the resulting condensation will be considerably reduced owing partly to the smaller temperature range in each cylinder and partly to the fact that the heat transferred from the walls of the high-pressure cylinder to the steam during the exhaust period is utilized in doing useful work in the low-pressure cylinder, instead of being wasted as in the case of a simple or single cylinder engine.

If steam at an initial pressure of 100 pounds is admitted to the high-pressure cylinder and expanded down to 35 pounds, then exhausted into a second, and expanded to 2 pounds, the temperature range in the first cylinder will be 338—281= 57 degrees, and in the second, 281—219=62 degrees. While the total temperature range is the same as before, that in the high-pressure cylinder is only about one-half as great, and we may assume the condensation to be reduced approximately in the same proportion.

As re-evaporation takes place to some extent as the steam passes to the low-pressure cylinder, the greater part of the wasteful condensation will take place in the second cylinder where the temperature range is only 62 degrees, as against 338—219=119 degrees in the simple engine.

High Pressure Economical

While the immediate effect of compounding is a reduction of cylinder condensation, another advantage which tends to reduce the steam consumption is the ability to use high initial pressure and higher ratios of expansion, both of which are in the line of economy.

A comparatively small amount of fuel is required to raise the steam pressure from 80 or 90 pounds, the common practice for simple engines, to 120 or 160 pounds, which may be used to advantage in those of the compound type, thus increasing the power of a small cost.

The actual gain in economy by compounding non-condensing engines will usually run from 10 to 15%; hence, in using Table IV, multiply the figures by 0.85 to 0.92.

The disadvantages are the higher first cost, the greater number of parts to care for, increased space, and greater radiation losses. The types most commonly employed where space is limited are the tandem and angle engines,

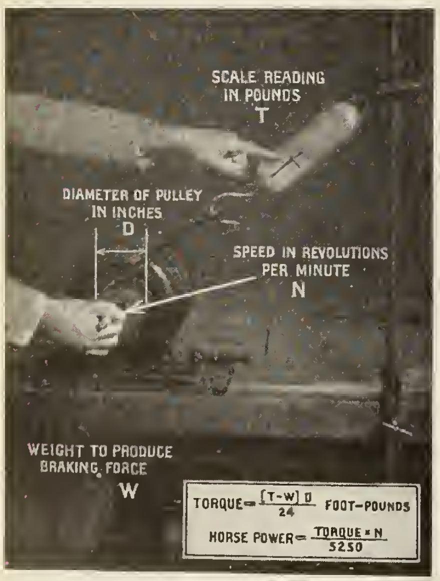

Figure 8: The horse-power of small engines is measured directly with a Prony brake. This laboratory model shows the principle upon which it works.

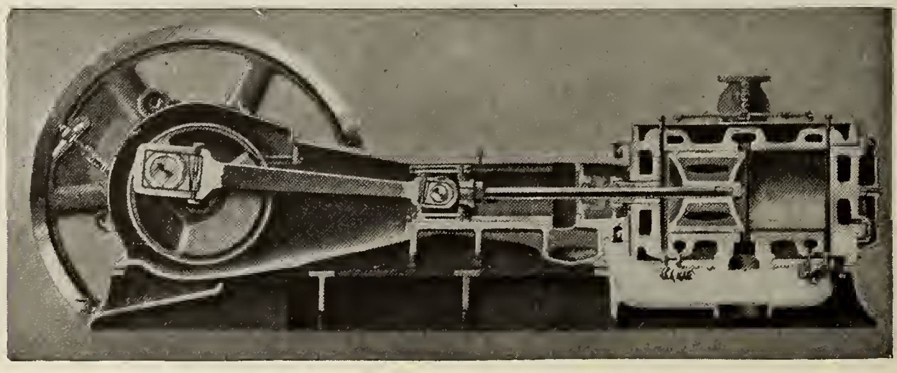

Figure 9: Multiple expansion engines involve complicated mechanical construction and increased cost. In the uniflow engine, however, reduced cylinder condensation is obtained without superheat and simplifies the mechanical construction at the same time, as this illustration well shows.

shown in Figures 7 and 4 respectively.

Cross compound engines are made up of two complete machines (see Figure 5), except for the main-shaft and flywheel, and, therefore, require more floor space.

Effects of Condensing

Now a word as to the effect of condensing. So far as the design of the engine itself is concerned, there is no difference between the condensing and non-condensing types, the only distinction being that in the first case the exhaust pipe from the engine is connected with a condenser instead of discharging into the atmosphere. If 24 inches of vacuum is maintained in the condenser, the back pressure will be reduced from 16 or 17 pounds absolute to 3 pounds absolute. As this reduction in back pressure extends throughout the entire stroke it is equivalent to increasing the mean effective pressure at least 16—3=13 pounds per square inch. The vacuum commonly maintained in average practice, with reciprocating engines, will run from 22 to 26 inches, depending upon various operating conditions. The lower figure corresponds to that obtained by the equipment usually employed with engines under 100 h.p., and the higher for larger sizes.

Depends on Vacuum

The gain in economy by the use of a condenser will depend upon the degree of vacuum maintained and the mean effective pressure of the engine when running non-condensing. This, under ordinary conditions, should, theoretically, vary from 20 to 30%, but is found to be considerably less in actual practice, and will run from 12 to 15% in the case of simple high-speed engines, up to 21 to 24% for slow-speed compound machines.

The saving for medium-speed simple engines will be from 15 to 18% and 18 to 21% for compound engines of the same type. These figures may be used in connection with Table IV when computing the water-rate for condensing engines.

Engines are designed to operate most economically at a given ratio of expansion. When working at a given speed and initial pressure, any reduction of load in case of an automatic engine is offset by shortening the cut-off, thus increasing the expansion and temperature range which results in lowering the steam economy through increased cylinder condensation and decreased mechanical efficiency.

Table V gives the approximate effect of underloading non-condensing engines, and may also be used for condensing, as the variation will be slight.

Table V

Type of Engine	Ratio of steam consumption per i.h.p. to that at full load for different underloads.		
	¾ load	½ load	¼ load
Compound high-speed	1.03	1.21	1.78
Simple high-speed	1.01	1.07	1.23
Compound low-speed	1.09	1.32	1.88

Theoretically, the efficiency of an engine increases with the temperature range.

In actual practice this does not hold true because a point is reached where cylinder losses more than offset any gain in steam economy. Furthermore, the cost of construction and maintenance increases rapidly at the higher pressures. Practical experience has fixed certain limits which are usually followed in the design and construction of the different types of machines. These are about as follows:

Table VI

Type of Engine	Initial Pressure (gage)
Simple high-speed	80 to 120
Simple low-speed	70 to 110
Compound high-speed	120 to 160
Compound low-speed	150 to 190

Ratio of expansion, like the initial pressure, has been fixed by practice and may be taken as follows:

Simple non-condensing	3 to 4	expansions
Simple condensing	4 to 5	"
Compound non-condensing	10 to 12	"
Compound condensing	14 to 18	"

U.C.C. of E. Banquet in Toronto

Canada Council and Queen City Council Entertain Hamilton Members in Oddfellows Hall

GOOD-FELLOWSHIP was the outstanding feature of a banquet on Nov. 19, in Oddfellows Hall, Toronto, when Canada Council and Queen City Council, No. 27, U. C. C. of E., entertained members and guests from Hamilton council, No. 60. Few meetings have been jollier and certainly none have been more successful in cementing the bonds of friendship and promoting the spirit of progressiveness abroad.

After a brief business meeting of Canada Council, about 120 members and visitors sat down to a delicious repast supplied by Queen City Council. Song sheets, which included all the old favorites, were distributed, and when the ever delightful Herb E. Terry led the singing, ably assisted by Howard Fletcher at the piano, it was evident to everyone that engineers are truly only grown up boys.

Worthy Chief Charles L. Holmes, who was chairman and toastmaster, opened the evening with a toast to H. M. the King. S. Cosford of Hamilton followed with a toast to the Grand Council. J. L. Cudbird, Grand Guard of the Grand Council of America, after patiently enduring a five minute barrage of "He's a Daisy," when he rose to speak welcomed the visitors and emphasized the advantages to be gained by the organization of a ladies' lodge in the "Pittsburgh of Canada," similar to Queen City Lodge in Toronto. He reminded those present of the annual convention next August in Chicago, and pointed out how vitally interested every member should be in enlarging the scope of the U. C. C. of E. in Canada.

Grand Chaplain Replies

Thos. McAree, Past Worthy Chief, proposed the toast of the Ladies' Grand Council, which was responded to by Mrs. George Aldridge, Grand Chaplain. "There is opportunity for everyone to become a grand officer of this splendid organization, if they only work hard enough," Mrs. Aldridge asserted, urging those present to attend the national convention.

Mrs. A. M. Auchterlonie, president of Queen City Council, the next speaker, demanded the "men of Hamilton" induce their ladies to organize a lodge. Thirteen new members have been initiated in the Toronto lodge alone this year and Queen City ladies, Mrs. Auchterlonie said, are looking forward with anticipation to the time when they can be entertained by Hamilton.

The honor of giving the last toast was awarded Past Grand Worthy Chief Terry, and he aroused enthusiasm by asking members to welcome the visitors with three hearty cheers. Alex. Leckie of Hamilton, coyly suggested in replying, that it probably would be wise for Toronto engineers to bring their ladies with them when they went "visiting." Thos H. Fenner, in a brief speech, declared he hoped to be a member of the U.C.C. of E. before the dawn of another banquet. Campbell Bradshaw, of "Power House," in thanking the "fair ladies" and "strong men" for their hospitality, said he only wished his newspaper occupied the niche in the journalistic field that the U.C.C. of E. occupied in fraternal circles.

Ladies Stimulate Interest

R. B. Hornby, of Hamilton, a stalwart champion of women's rights, said he thought the ladies gave the meeting more spirit and stimulated interest in the "doings" of the lodge—"no longer are the circulars stuck behind the kitchen clock till the day after the meeting," he declared.

Mr. Holmes, in the final speech of the evening, thanked the ladies for an excellent repast.

Delightful solos were rendered during the evening by Mrs. Albert Darbyshire, Miss Gladys Blythe and Miss Dora Ball, and after supper the floor was cleared and the "Power House" orchestra appeared. Everyone joined in a good old "Paul Jones," and went home wishing the U.C.C. of E. "Godspeed" in all the years to come.

W. F. Drysdale was the speaker at the Electrical Club of Montreal, at a luncheon at the Queen's Hotel, Nov. 28.

The Mildmay Electric Co., Mildmay, are in the market for transformers and equipment for a proposed extension. D. McKerracher, Walkerton, Engr.

Endorse Stand of Power House on Boiler Law

Ontario Manufacturers, Engineers, and Insurance Men Demand Proper Inspection—Deputy Minister of Labor Ballantyne Admits Dual Control is Bad and Declares He'll Recommend Change to Dr. Godfrey

THAT the Conservative administration at Queen's Park has promptly heeded the warning, sounded in the June 5 issue of Power House, deploring the ridiculous and expensive division of authority in the inspection of steam boilers and pressure vessels in Ontario, was apparent from the conference called by the Department of Labor on Nov. 19 to consider the "holes" in the law exposed in the article in question.

Invitations to the parley emanated from the office of James H. H. Ballantyne, deputy minister of labor, and included all parties interested in the design, construction, sale and operation of steam boilers and pressure vessels, representatives of Power House being asked to take part in the proceedings at Spadina House.

That the conference included all factions, affected by the legislation, is apparent from the following list of those present: James H. H. Ballantyne, deputy minister of labor; D. M. Medcalf, chief boiler inspector; James T. Burke, chief factory inspector; R. Burns, boiler inspector; A. R. Goldie, Wm. McKay, and Arthur K. Spotton, of Babcock-Wilcox & Goldie-McCulloch, Galt; William Inglis, John Inglis Co., Toronto; Colin Campbell, Campbell Steel and Iron Works, Ottawa; Ibbotson Leonard, E. Leonard & Sons, London; Logan M. Waterous, Waterous Engine Works, Brantford; C. W. Snider, Waterloo Mfg. Co., Waterloo; J. E. Waterhouse, Engineering & Machine Works of Canada, St. Catharines; M. J. Quinn, National Equipment Co., Toronto; F. W. Sherer, Dominion Boiler and Radiator Co., Toronto and Brantford; M. J. Levy, Levy and Westwood Machinery Co., Toronto; Henry R. Flett, Taylor Forbes Co., Toronto; A. Taylor, Boiler Repairs, Toronto; H. Macdonald, Canadian Manufacturers' Association, Toronto; H. M. Roberts, Boiler Inspection and Insurance Co., Toronto; A. Mills; R. Fullerton, Travelers' Indemnity Co., Toronto; J. O. B. Latour, Employers' Liability Assurance Corporation Co., Toronto; Geo. J. Soucy, Canadian Association of Stationary Engineers; J. H. Valin and H. E. Leverington, hoisting engineers; J. H. Bell, stationary engineer; J. M. Brown, chairman of the Board of Stationary Engineers; and Arthur Murphy, editor of Power House.

After explaining briefly his reasons for calling the meeting and thanking those present on behalf of the Department of Labor, Mr. Ballantyne was appointed chairman, and the success of the conference is due largely to the capable manner in which he presented the questions for consideration.

Seeks Weak "Spots"

In his opening remarks the deputy minister of labor pointed out that before any changes were made, the existing legislation should be thoroughly examined and its weak points studied so that all parties affected might have opportunity to discuss the matter.

"You are aware," said Mr. Ballantyne, "at the present time there are two Acts which deal either in whole or in part with the boiler industry within the province. The one is The Steam Boiler Act, and the other is section 57 of the Factory, Shop and Office Building Act. The very fact of having two statutes dealing with the boiler industry, either in whole or in part, implies a duality of functions within the Department.

Every effort is being made to fill the pages of Power House with articles, ideas, news, and so forth, of value to engineers. Because of this, send suggestions, ask questions, look upon the paper as your very own. Any time anybody wants anything, write in, every effort will be made to get it for you. And another thing: Send news, ideas you are using, pictures—anything of interest to others. And what are others interested in? Why, they are interested in the things you are interested in.—THE EDITOR.

"The Steam Boiler Act and Regulations deal specifically with the construction and inspection of new boilers—using the term 'boiler' in the sense that it is defined in the Act—and it also deals almost exclusively with second-hand boilers bought, sold or exchanged."

The minister dealt briefly with the problems of annual inspection, the inspection of steam boilers by stationary engineers, and the responsibility of the owner in regard to annual inspection.

Mr. Medcalf then pointed out the defects of the present system, as he saw them, emphasizing the fact that endless confusion and irritation resulted from the dual control within the department, and that the failure of the present inspection system was due in large measure to it.

Explains Working of Act

Mr. Burke explained the working of section 57 of the Factory Act in its relation to the inspection of steam boilers. At present if a boiler is insured with one of the authorized boiler insurance companies it complies with the statute, or it may be inspected by a qualified engineer who is not in charge of the boiler as operator and in addition, by Order-in-Council, by an inspector of the Steam Boiler Inspection Branch.

"We have no boiler inspectors," said Mr. Burke. "If there is any weakness at all it is probably in that part of the statute, but I find from our files that in our fiscal year just closing, we received the inspection of 1442 boilers and 257 pressure vessels. This matter of course relates to engineers' inspection and I find that the inspections were made by 14 first-class engineers, 340 second-class engineers, 91 third-class engineers, 10 fourth-class engineers and 6 hoisting engineers.

Mr. Burke then showed that the province was gradually approaching a condition similar to that which exists in England where a large percentage of the boilers are insured. He also maintained that the right to make boiler inspections should not be taken from the stationary engineer, because in his opinion it might work hardship in many cases and he considered the stationary engineer more capable than an outsider of making the inspection.

Mr. Medcalf questioned several of Mr. Burke's statements, giving specific cases of boiler explosions which were not included in the chief factory inspector's report.

Victims Every Year

"There is no year passed but had some persons killed in explosions," stated Mr. Medcalf. "I can go through every report to show you that this boiler inspection should really come under the jurisdiction of the Boiler Inspection Department. I venture to say that we have had 15 explosions in the last ten years that were not mentioned at all by Mr. Burke, showing that the factory inspectors really do not know about these explosions when they occur. For example, there were three explosions this past year that they know nothing at all about."

A general discussion of the Act followed the explanations of the working of the two branches of the department.

Mr. Soucy maintained that stationary engineers were not as a class capable of inspecting boilers, but that they should be required to pass an examination to determine their capabilities, proving his statements by citing cases that had come to his attention where the safety valves had been tampered with.

In one case, referred to by Mr. Soucy, the safety valve was loaded down with bricks, pieces of iron and other weights so that it could not be opened without an enormous pressure. In another case, the safety valve was held down by a stick from the ceiling to the lever of the safety valve. This latter example was in an office building in Toronto where several hundred people are employed every day.

Wants One Branch

Wm. Inglis thinks boiler inspection ought to be all under one branch. "Why have two departments?" asked Mr. Inglis. "When you start to build your boiler, an inspector of your department looks after the whole thing. Why can't you get inspectors to carry out the whole thing in accordance with the regulations of each province? It is carried out in that way in accordance with the new Act they have for all Canada. The Interprovincial Act covers the whole thing. They have their own inspectors in the different provinces, and we cannot carry it out in this province unless we follow the example of the other provinces. With the interchange of boilers from one province to another province there is no jurisdiction over them. I think that the whole thing should be under the Steam Boiler Branch."

In reply to Mr. Soucy's statement that there were many boilers in the province in a dangerous condition, due to lack of proper inspection, the chairman asked how many inspectors it would take to carry on an inspection such as was outlined, pointing out the enormous size of the province and the expense that would be incurred keeping a staff of inspectors large enough to check up violations.

"At the present time we have a staff of 19 factory inspectors, limited in their power so far as they may enter or keep out of certain places and they do not cover adequately the province so far as adequate inspection of steam boilers is concerned even in reporting violations, far less dealing with the violations themselves," said Mr. Ballantyne.

Discussion followed along general lines for some time, various questions in regard to details of the working of the Act being brought up and no little time was devoted to criticism of officials of the department.

To Shelve Criticism

J. E. Waterhouse summed up the discussion by saying, "I do not think that we can get anywhere by criticizing department officials. It seems to me here is the situation in a nutshell: we have the Steam Boiler Branch that receives blue prints of boilers and specifications. That branch O.K.'s them or not according to their merits, oversees the construction of boilers according to these plans and specifications, up to the point of completion; then has absolutely nothing to do with that boiler again unless it should undergo extensive repairs or be removed. At the point of completion the boiler comes under another branch. Both of these branches may be efficient in the extreme,—we have no reason to believe otherwise, and yet it is not a commonsense situation. The record pertaining to a boiler should be under some official or under some branch from the time the blueprints are approved until that boiler goes out of use."

In reply to the question of Arthur Murphy, asking if any good reason existed for having dual control, Mr. Ballantyne said he did not agree as the head of the department with the duality of function.

"As a matter of principle I think it is a bad thing and I am prepared to recommend to Dr. Forbes Godfrey that a change be made."

Several good suggestions were made by Mr. Waterhouse to secure efficient inspection and check up violators of the Act, by making use of the factory inspectors to report through Mr. Burke to Mr. Medcalf any cases which came to their attention. It would add practically nothing to the work of the factory inspectors and would certainly cut down the expense of the work.

Divide Up Province

Mr. Burns suggested having the province divided into districts or zones with an inspector in each, in that way tending to keep the inspection fee uniform, and as each inspector would be kept busy the whole time, the system would be self-supporting.

Ibbotson Leonard stated that a gentleman from British Columbia assured him that their department was self-supporting and brought a small revenue to the province, and if that system worked out satisfactorily in British Columbia he could not see why it should not work out satisfactorily in Ontario.

M. J. Quinn in reply to questions regarding the enormous expense which might result from attempts to have an efficient inspection system, said that the very basis of this question was to bring out means for protecting the public and no matter what it cost, the people that it serves would bear the expense.

"Is it going to be by distributed authority or splitting it up against various departments, or going to be by centralizing or making laws of such a character that one department will know that every boiler is safe within the meaning of the Act. I want to move a resolution, if it is in order, and I think it is one that might properly come before the meeting, that in the judgment of this meeting, it is desirable that inspection of boilers and pressure vessels shall all be placed under the Boiler Inspection Department of this province, but I want to add a rider to that, an expression of opinion, that the factory inspection department should be used and utilized to the fullest possible extent."

This motion was seconded by Mr. Leonard and carried without a single dissenting vote. The meeting then adjourned until the afternoon, the morning session having brought out two main issues; first, that all parties interested in the manufacture, sale, or use of steam boilers, represented at the meeting, desired a change in the laws dealing with the inspection of boilers, and that all inspection of boilers and pressure vessels in the province should be under the control at all times of the boiler inspection department.

Discuss Proposed Act

The afternoon session was taken up discussing the proposed act respecting steam boilers which was tentatively approved by a conference in 1915. H. M. Roberts stated that the copies of the proposed act, distributed at the meeting, differed quite materially from that of 1915.

Acting on the suggestion of the chairman, an attempt was made to define the term steam boiler. Mr. Leonard suggested that to facilitate matters it would be better to designate the act as "An Act referring to steam boilers and unfired pressure vessels," and moved that this act be adopted. Wm. Inglis seconded the motion.

Mr. Roberts said that certain changes were desired by the insurance companies and considerable change in details would have to be made, so that it would be best to refer the act to a committee before final adoption.

Of vital importance to the Canadian manufacturer is the problem of proper inspection of boilers imported from the United States.

J. E. Waterhouse here offered the suggestion that the Department of Customs be utilized to inform the Chief Boiler Inspector when and where any boiler had entered the Dominion. The boiler inspection department could then deal with the matter.

Boilers shipped from Quebec to northern parts of the province frequently escaped inspection, which was unfair to Ontario manufacturers.

The inspection of boilers when installation has been completed met with the approval of all at the conference. In this way not only the boiler, but the whole piping system of a plant would be inspected.

Urges Advisory Board

Mr. Roberts suggested that an advisory board representing all parties interested in steam boilers and pressure vessels should advise the steam boiler branch and make recommendations to the minister respecting the design, construction and installation of boilers, but not to interfere in any way with the carrying out of the regulations.

Mr. Medcalf stated that he would welcome any advance along these lines, but seemed to fear that such a board might overstep its powers. "I can not welcome any interference with the regulations," he said.

Registration of all boilers in the province was favored; however, subsequent discussion brought out that annual inspection of all boilers would automatically look after it.

Easy Engineering Lessons in the Power House

By M. BARRY WATSON, B.A.Sc., M.E.
Director of Engineering, Central Technical School, Toronto.

ALL boilers should have at least one thorough inspection, as well as several external inspections each year. This is necessary to insure that no undue corrosion or weakening of the stress-carrying parts of the boiler has taken place.

If all operating engineers were trained in the inspection of steam boilers, and could be depended upon to inspect their own boilers regularly and thoroughly, and to make, or have made, any necessary alterations or repairs before the safety factor of the boiler dropped to any extent, there would be no need for government inspection to insure the safety of the public, nor of boiler insurance to indemnify the owners against loss in case of boiler explosion, because there would be little chance of explosion.

It seems, however, that humans are much more thorough in inspecting someone else's work, or a plant with which they are not over-familiar, than in the inspection of their own work or plant, no matter how conscientious they may be. Thus, it is apparent that boiler inspection must continue.

In Ontario, the Factory, Shop and Office Building Act stipulates that no boiler, except private house heating boilers and those used purely for agricultural purposes, shall be operated or used unless it is insured with one of the companies licensed to insure boilers in Ontario, or has been inspected within one year by a boiler inspector appointed by the Department of Labor for this purpose.

Up to the present time there have been no inspectors appointed under the above regulations, but an order-in-council is effective whereby persons holding Ontario stationary and hoisting engineers' certificates are permitted to inspect boilers under the above regulation.

The author will not here give his opinion as to the value of inspection by any person holding the Ontario certificate, suffice it to say that even in the examination for first-class stationary engineers' certificates the candidate is not examined on his ability as a boiler inspector.

A boiler inspector must be able to accurately determine safe working pressures for boilers in all sorts of conditions, and it is likely that most holders of stationary or hoisting certificates would not have the least idea of how to commence such a determination, let alone knowing how or where to look for weakening in the boiler parts.

Insured Boilers Safe

It is quite safe for the Department of Labor to depend on insured boilers being in safe working condition, because the insurance companies are not going to take any more chances than they can help, and will make sure through their inspectors of the condition of any boiler, and will not insure it unless it is safe at the pressure at which it is to be operated.

A boiler inspector should never condemn a boiler. The most he should do is to calculate a safe working pressure after he knows thoroughly the condition of the boiler and specify that the safety valve must not be set to blow off at a higher pressure.

If this specified pressure turns out to be too low for the purpose for which the boiler is used, the owner will do his own condemning, or else will have repairs made or the boiler rebuilt so the inspector will allow the necessary pressure. Any factory inspector appointed under the Ontario Act has, however, the power to order the discontinuance of the use of any boiler which he considers unsafe, until it is inspected by a boiler inspector who must issue a certificate showing at what pressure the boiler may be safely operated.

Makes Inspection Easy

If the engineer in charge of the plant makes the inspector's work as clean and easy as possible and co-operates with him and anticipates his requirements, it is quite natural that the inspector should give a better report on the condition of the plant and allow more latitude to such an engineer than would be the case if he were inspecting a boiler where the engineer had made little preparation for the inspection and obstructed rather than helped the inspector in his work.

It is quite right that such should be the case, for if an inspector finds that the engineer in charge of the plant is on the lookout for trouble, and knows where to look for it and how to remedy it, he is fairly well assured that the plant is in good hands and will be perfectly safe.

On the other, if the engineer rubs the inspector the wrong way, gives him dirty furnaces and boilers to crawl through, tries to hide or keep him from finding some fault or defect which may reduce the safety of the boiler, or otherwise fails to co-operate with him, it is likely that the inspector will not give a good report, or may even require a further reduction in allowable pressure as an added safeguard.

Cover Up Defects

There are some engineers who feel it their duty to their employers to try to cover up defects from the eye of the inspector and thus prevent him obtaining a thorough knowledge of the condition of the boiler, thinking that in this way they can prevent the reducing of the working pressure by the inspector.

In such instances the inspector usually plays safe and cuts the allowable working pressure low enough to make sure of taking care of possible hidden defects, which pressure is probably lower than he would allow if he knew the complete condition of the boiler; thus the engineer would really be defeating his own object. It must be remembered that the owner, in the case of insured boilers, is paying out money to have his boilers inspected and thus assure himself that they are in good shape, but if his engineer reduces the effectiveness of these inspections he is really disloyal to his employer and is wasting that money. Also, if defects should be hidden from the inspector and an accident happen in respect thereof, it would be more difficult for the owner to get any further boiler insurance, and more difficult still for the engineer to get another job if he survived to look for one.

Find Co-operation Best

On consideration of the above points it would seem that the most complete co-operation with the inspectors is the best for all concerned. On the other hand, there are people in the world who are naturally suspicious of everybody. The writer has met boiler inspectors of this type, and the more one tries to cooperate and help such an inspector the more suspicious the inspector becomes that the engineer is trying to "put something over" him.

The writer once tried to help an inspector in every way possible, helped him scrape the shell, held his candle for him and did everything possible to assist. The inspector in question gave that boiler such a thorough inspection as the writer never saw before or since, many parts twice or three times. Finally, the writer was quite taken back when the inspector said: "Whatever it is you are trying to hide by sticking so close to me, I cannot find it so you might as well tell me what it is."

Luckily such inspectors are few and far between, but one should be careful not to force unwelcome attentions on an inspector for fear he might begin to suspect one of duplicity.

The object of this lesson is, therefore, to impress on engineers the advisability of co-operating with the boiler inspectors, and to tell how this may best be done without antagonizing the inspector.

Washed Clean Inside

Before a boiler can be inspected it must be cooled down, emptied, and washed clean inside, and the outside of the shell and the whole setting should be brushed and cleaned of all soot and ashes.

A worth-while preliminary step in the cleaning of the boiler is to blow down a couple of gauges of water while the boiler is still making steam. While in this condition much of the dirt in the boiler is being agitated and moved about slightly by the formation of the steam and in this condition it is more likely to be washed out with the current of water toward the blow-off pipe than after the dirt has had a chance to settle close to the bottom of the boiler.

In endeavoring to cool a hot boiler some engineers make the mistake of opening the cleanout and smoke-front doors, thus bringing cold air in direct contact with the tube ends. They then wonder why they are troubled with leaking tubes and tube sheets when they are operating next time.

The proper procedure is to keep the furnace doors closed after the fire is drawn, open the damper and allow cold air to enter through the ash pit in the usual way.

Thus, all the air used to cool the boiler passes through the hot furnace before it reaches the boiler, and is partly warmed up, causing less strain on the various joints, etc. After the setting is cooled down to such an extent that it no longer warms up the air appreciably the boiler will be cool enough to be unaffected by cold air.

Pressure Drops to Zero

As soon as the steam pressure has dropped to zero, let the water run out of the boiler through the blow-off, opening the safety valve or the try-cocks to allow air to enter the boiler. As soon as possible break in the manhole cover, and remove it as soon as the cloud of vapor which arises has subsided sufficiently to allow of it being done.

Remove the other manhole and handhole covers and allow air to circulate through the boiler to both cool and dry it. By this time the fire doors and back clean-out doors may be left open, but the smoke-front doors should be kept closed, except while the manhole or handhole is being opened.

Much of the cleaning of the outside of the boiler cannot be attempted until the furnace and combustion chamber are cooled sufficiently for one to work therein. This necessary cooling will be hastened considerably if the ashes and dust are removed as much as possible by means of a long-handled shovel, and the bottom and heads of the boiler are swept off with a broom.

As soon as the smoke-front doors can be left open the tubes should be thoroughly cleaned.

Do not "blow out" the tubes with steam from another boiler after they are cool, because this steam will heat up the boiler again, at the same time condensing in the tubes and forming a gummy mixture with the soot and dust. Compressed air is good for this purpose, if available. The tubes must finally be "punched" or scraped and brushed out.

Remove All Dirt

All dirt should be removed from the furnace, combustion chamber, smoke-front, etc., the sides of the setting and all parts of the shell of the boiler should be scraped and brushed clean. A sawed-off broom will be found very convenient for cleaning the bottom of the shell and side walls.

The whole setting should be made as nearly perfectly clean as possible in order that the inspector may not be bothered wading through dirt and soot nor have to waste time cleaning the plates in order to examine them closely.

In cases where it is impossible to wait long enough to cool down a boiler, as detailed above, it may be hastened by letting down the steam pressure by easing off the safety valve.

In this way much of the heat contained in the boiler is used up in forming low pressure steam, in which form it escapes. It may also be found necessary to allow a free circulation of air as soon as the fire is drawn, but this is not advisable if it can be helped in any way.

It must be remembered that air entering the fire doors or the clean-out doors will cool the boiler far more than air allowed in the smoke-front doors, which merely rubs against the head of the boiler and kills any draft as far as the tubes are concerned.

After pressure has been brought to zero by allowing the steam to escape, the boiler can be emptied through the blow-off, and the manholes and handholes can be opened at once to allow circulation of air in the boiler. If emptied by the quick method, hot water should be used for flushing out. This may be obtained from another boiler below the water line, or from a separate heater, or part of the steam wasted in lowering the pressure may be led into a large water tank to heat the water for washing out. This latter is the most economical method if one has the tank available. If the boiler has been allowed to cool thoroughly, cold water may be used for flushing out.

This should be done with a hose under as high pressure as possible in order to remove the greatest amount of dirt possible. In washing out, a note should be

UNCOVERED IN ANY OLD SPOT

They had to carry Carl to the carriage;
The carriage carried Carl to the door;
The reason they had to carry Carl to the carriage,
Was because Carl couldn't carry any more.

* * *

When installing an oil engine have a foundation of sufficient size. Many engines are damaged from severe vibrations which would be eliminated by using more foundation material.

* * *

The man who once most wisely said,
"Be sure you're right, then go ahead,"
Might well have added this, to wit:
"Be sure you're wrong before you quit."

* * *

Unlike the steam engine or steam turbine which show a large increase in fuel per brake-horsepower as the load drops, the Diesel has an excellent low load efficiency. For this reason the Diesel is economical on changing loads.

* * *

The man who gives in when he is wrong, is wise. The man who gives in when he is right is generally married.

* * *

If a semi-Diesel is operated with a low temperature cooling water discharge it usually smokes badly and will not carry its load. The engineer should experiment until he secures the temperature for best results.

* * *

Her name was Irene
And she wore crepe de chine—
You could see more Irene
Than you could crepe de chine.

* * *

The fuel consumption of the usual semi-Diesel of over 100 hp. is approximately 0.6 lb. of fuel per horsepower-hour. Large semi-Deisels have shown a fuel consumption as low as 0.50 lb. per horsepower-hour. Small engines deliver a brake-horsepower on about 0.8 lb. per hour at full load.

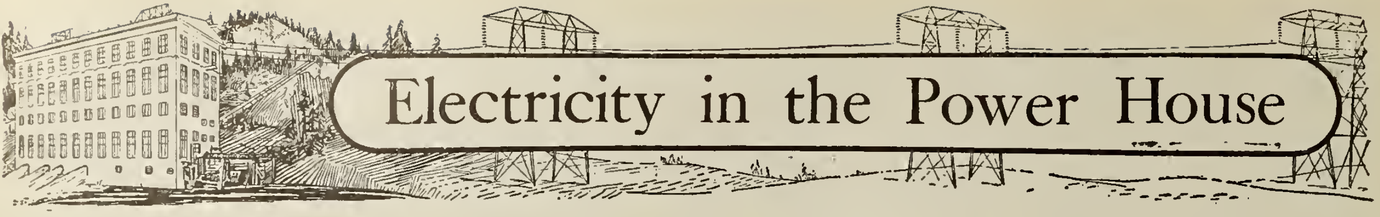
Some folks argue that advertisin' is an expense which must be charged agin' th' consumer. It's a two-to-one shot that these folks try to sell last year's goods this Christmas.



Electricity in the Power House

By J. A. BURNETT, M.E.I.C., Consulting Engineer, 205 St. James St., Montreal

RUNAWAY ENGINE

A CASE of trouble with an engine recently came to the attention of the author. This particular engine was a small, high-speed piston valve type, directly connected to a 75-k.w. lighting machine, normal speed 270 r.p.m.

When this outfit was started and the engine given full steam pressure, the first speed would probably be 276 and as quickly as another reading of the speed could be taken 281, then 287, 293, 297, 301, 310, continuing to creep up slowly.

With any load from 10 k.w. up, the speed regulation was very good, but whenever the load was thrown off the speed would begin to creep up. It was run throtttled until all of the parts had reached an even temperature, but with no better results. The engineer then took out the valve to look for steam leaks but it seemed to be in good condition. A trial showed that the condition had not been improved.

An improvised device showed that the governor did its work so that it looked reasonable to believe, despite the indicator cards, that there must be some error in the valve setting.

This was checked over, the piston being taken out and examined. Cards were taken until there was no more paper to fit the indicator. The trouble continued for three or four days, until a theoretical curve, such as engine builders send out, was found.

In comparing the card with one of the no load curves the trouble was as apparent as though it had been printed in words across the paper.

The valve leaked steam. The valve was taken out for the second time and the inside of the rings peened to spread them out thereby increasing the pressure against the walls of the steam chest. The problem was solved, for no engine could run better than this one does now.

VICIOUS COMMUTATION

It is no uncommon thing to nurse a piece of apparatus through the rush hours and then spend the rest of the day in tearing it to pieces and hustling to get it together for the heavy loads of the morrow.

In large cities where the street cars must be kept moving and the lights kept burning as long as machinery will deliver power, chances are taken that fairly startle one in the calmer moments of reflection.

An instance of this sort once happened when an engineer wandered aimlessly into a station where he had started a small rotary converter for street car work some ten or twelve days previously.

He was very much surprised to find that with any load the brushes would spark viciously. Shifting them either way to find a better point of commutation made no difference.

The commutator was in bad shape, but even this failed to explain why the machine should behave in this manner when it had satisfactorily handled a much heavier load only a week before. A few hours finished the days' run and a careful examination revealed the fact that only seven out of the twenty-four brushes were touching the commutator. For some reason the brush tension had been increased to such an extent that the brushes had been ground away until the nuts which fasten the carbon to the copper shunts would not let the brush slide farther down in the holder.

The cause of the sparking on the heavy loads was clearly due to the lack of sufficient brush area for carrying the current.

Since no extra brushes were at hand it took the best part of the night to smooth off the commutator and put the machine in a workable condition.

LOOSE BRUSH HOLDER

Elevator work is more or less troublesome, because these motors are not, as a rule, installed by the makers and if anything goes wrong, it is usually attributed to a supposed defect in the machine.

A short time ago the writer was asked what could be done with a small direct current motor in elevator service which was unsatisfactory.

On reaching the place all hands were awaiting his coming. They claimed that the motor seemed to run away and that the brushes threw off sparks like a blast furnace.

The control outfit was of a complicated design, the wires being so concealed that it looked to be a three or four-hour puzzle to find out where they went.

Before an actual demonstration was made a happy thought prompted an investigation of the brushes and there they were, just half way between the neutral points, so that running the motor in either direction produced a furious sparking. It did not take long to remedy the defects.

Speedy Elevator

Another similar case occurred where the man in charge of the installation insisted that the motor was wired according to the diagram and since the elevator ran about four times its proper speed, there was undoubtedly something wrong with the motor.

Like the experience just cited there was litttle difference in the speed whether the car was going up or down.

A drop across the shunt field revealed the trouble at once. The connections were such that less than 25 per cent. of the line voltage reached this part of the motor, and when the foreman stated that he did not see how this could make any difference, it was necessary to make the changes in the wiring to demonstrate to him that there was nothing wrong with the machine.

Convention Notes

THAT there has been no decline of interest upon the part of members in the work being carried on by the National Association of Ice Industries was evident by the large attendance at the sixth annual convention of the association, at the Hotel Winton, Cleveland, Nov. 13-16. It is probable the record attendance at Chicago last year was broken, 680 delegates being recorded as present. Every state in the union was represented and there was a strong delegation from Canada.

There was an overflow at every general session and the group meetings were also well attended. Throughout the entire convention the deepest interest was manifested in the questions of nation-wide importance to the industry covered by the reports of officers and standing committees.

The outstanding features of the convention were the adoption of a new constitution, and the action taken through a resolution passed by the convention and put into effect at a meeting of the board of directors to proceed with research work and to make arrangements for the testing of materials used in the manufacture of ice.

A pleasant incident connected with the meeting was the presentation to President Black of a token of the esteem in which he is held by the whole membership of the association.

Great satisfaction was felt by all members that the board saw fit to elect Mr. Black to the presidency for the third time and that it was possible for him to again accept the arduous duties of presiding officer.

Treasurer A. W. Broecker and Secretary Smith were also re-elected as were Vice-President Robbins and most of the regional vice-presidents.

Practical Ideas From Practical Men

REPAIRS DRAFT GAUGE

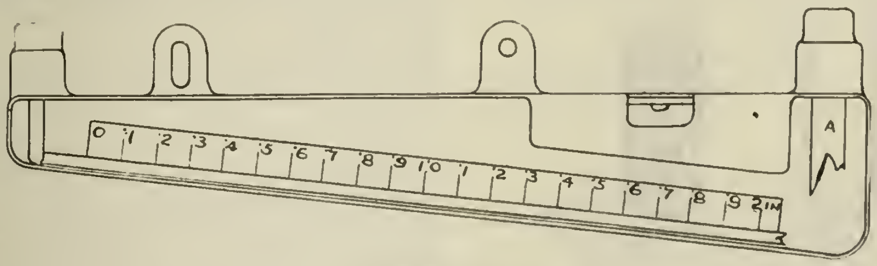
Some time ago we had the misfortune to break the glass tube of a differential draft gauge in our plant, through a careless fireman striking it with his rake. It looked a rather hopeless repair job with the facilities at hand, and getting a new tube meant a long delay and all kinds of bother.

'Tis said, however, that "necessity is the mother of invention" and the illustrations show how the problem was solved rather neatly.

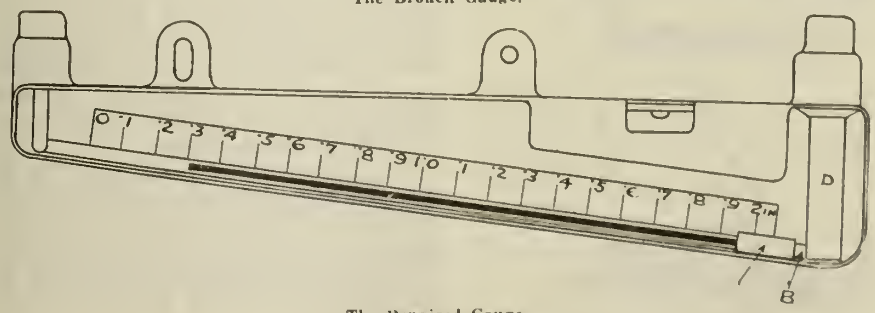
The internal diameter of the vertical part of the tube A was measured accurately, and a piece of thin sheet brass cut and bent into a tube of the same diameter, the joint being soldered and a bottom being soldered in.

A small piece of brass tube B of the same size as the inclined glass tube was then soldered in near the bottom as shown in the illustration. A piece of rubber tube C about ¾ in. long was then acquired from the Orsat apparatus and slipped on the end of the inclined glass. The glass tube A was then dug out and the brass one D slipped into place and secured at the top with ordinary putty. After the putty had hardened, a little thin shellac varnish was poured in and emptied out again, this operation being repeated three times, allowing an interval for the shellac to harden between each pouring, the object being to coat the rubber tube internally with shellac and protect it from the action of the oil used in the gauge, oil having been found very injurious to the rubber.

The repair has proved entirely satisfactory, though of course, it has reduced the capacity of the instrument slightly. This, however, does not trouble us, as we only use natural draft which is generally around .3 of an inch—THOMAS C. PORTEOUS, Michel, B. C.



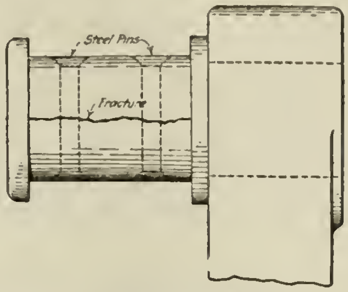
The Broken Gauge.



The Repaired Gauge.

REPAIRING A CRANKPIN

The crankpin of an engine for a long time had been giving trouble on account of heating. Often it had been necessary to turn a hose on the pin to prevent a shutdown before the close of the day. The engineer could discover nothing wrong with the pin; it was square with the crank and was round and smooth. Finally, the troublesome pin was removed and a new one put in.



Crankpin Repair.

But the engineer was not entirely satisfied that the new one was needed. As a last resort he examined the pin with a magnifying glass and found a fracture extending lengthwise of the pin almost from one collar to the other. The line of the fracture was so faint as to be almost undiscernible.

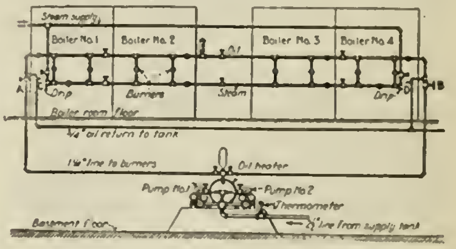
That explained the difficulty. The expansion of the pin as it warmed up to a running heat would cause it to spread out on each side of the fracture, thus making it bind in the boxes and cause excessive heating.

The pin was repaired as shown. Two ⅝-in. holes were drilled through it perpendicular to the fracture. The holes were countersunk and filled with close-fitting steel pins, heated to redness and riveted over at the ends. The riveted ends were then filed down to the curvature of the pin.—WALTER G. HUDSON, Montreal.

OIL BURNING LAYOUT

In our plant a complete oil burning system for four boilers has now been installed.

A storage tank of 100,000-gal. capacity is located a short distance from the plant, from which the oil flows by gravity to an underground tank of 6,000 gal. capacity. This tank is fitted with a heating coil, and the temperature of the oil is raised to 120 deg., live and exhaust steam being used for heating.



Layout of Pump and Piping.

Then the oil is handled by a 5¼ x 3½ x 5-in. duplex pump, which discharges through a heater to the burners. A duplicate pump is installed for stand-by service.

The heater is located between the pumps, and the temperature of the oil is raised to 200 deg. while passing through it.

Both the oil and steam piping are installed on the loop system. A return line is connected off each end of the loop between the discharge valve and first burner connection. In normal operation the valve A is open and the oil drains back to the suction tank through valve D, or the oil may be fed in the opposite direction by opening valves B and C and closing valves A and D.

There is a valve and union on both steam and oil line between each set of burners, for convenience in isolating or removing sections of the piping.

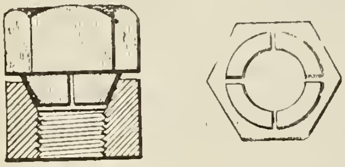
The burners are fitted with a valve and union on each connection and any burner can be removed and replaced in a few minutes, a spare being kept in readiness. A pressure of 100 lb. is carried on the discharge line from the pump, and a quantity of the oil is by-passed continuously to insure the proper temperature being maintained in the oil line. —A. W., Montreal.

LOCKING NUT

In some makes of steam hammer where the piston head and the hammer-block end are integral with the rod it is not unusual to form the gland casting in halves.

The intense vibration set up when the hammer is in operation renders difficult the permanent fixing of the gland nuts, these tending to work loose.

The writer tried double nutting, spring washering, and other familiar methods to check this tendency, but without avail.



Ultimately satisfactory results were secured by designing the form of check nut illustrated herewith.

A pair of ordinary ⅝ in. nuts were machined down to a conical male and female, the faces not quite abutting when set one upon the other. A double saw-cut slot was made across the conical portion of the male nut, which upon being locked by the female tended to close in a tapered portion of the male nut upon the threads of the gland stud, thus opposing any tendency for the nuts to work loose.

Two pairs of these nuts have been holding up a gland on a two ton steam hammer for the past two years without once slackening back.—GEO. SMITH.

PACKING HYDRAULIC RAMS

Herewith is a sketch of the lower parts of a hydraulic accumulator. Packing gland A is of the usual type packed with "cup leathers," but owing to the working surface of ram being slightly rough, the average life of each set of "leathers" was two months. I tried the following method with great success and can recommend it to anyone.

Take a piece of copper tubing long enough to make one turn of packing and flatten it out as shown in Fig. 2, then, carefully bend the flattened tube round ram allowing ends which should be cut at an angle (see Figs. 3), almost to "butt." Next cut the ring thus formed as shown in sketch, leaving the copper in the form of a U-piece sufficiently deep to fill packing box.

Fig. 4 shows U-piece filled with packing, which in my case was "Tuck's" with rubber core. This lasted for years. When setting up gland, see that the copper ring has been properly softened, also that packing is a tight fit in U-piece. The top turn should project for about two-thirds its diameter in order to allow for compression.

The best method to adopt in flattening copper tube is to fill it with lead, then pass it through rollers until the required dimensions are reached. This procedure tends to leave a more uniform surface than when the flattening is done with a mallet.

"Movies" Feature Power Show

Educational Exhibits Increase Interest of Engineers in Mammoth New York Exposition

INTEREST in the Exposition of Power & Mechanical Engineering at the Grand Central Palace, New York, Dec. 3 to 8, was increased by a series of educational exhibits and an extensive program of motion pictures. The subjects of the exhibits were fuels, steam locomotives, and modern high pressure boilers.

The exhibits of fuels were made up of specimens of the various kinds of fuels, solid, semi-solid and liquid with complete statement as to origin, and analysis. The solid fuels included a types of anthracite, semi-anthracite, semi-bituminous, and bituminous coal. The section of solid fuels contained samples of splint and cannel coal, dried peat, wood logs, faggots, wood mill waste, and various forms of briquetted coals. Prepared fuels, such as charcoal and coke, were shown as well as powdered fuels.

The exhibit of modern steam locomotives consisted of pictures and drawings, showing the development of the locomotive from its earliest stages down to the large machines of to-day. Various locomotive companies and railroad organizations co-operated in making this exhibit complete.

Showing of high pressure boilers consisted mainly of drawings of foreign and American designs, which have been in use or are at present being installed. The exhibit proved very instructive to all those who are following the rapid advances in steam power plant practice.

The manner in which valve manufacturers have solved the problem of valves and fittings for the high temperature steam plants, which modern economy demand was clearly displayed.

To Withstand Pressure

The features of this equipment to withstand extreme temperatures and pressures included sectionalized valves of steel and monel metal. One exhibitor showed a monel mounted globe valve for operating conditions of 400 lb. working steam pressure and 800 deg. Fahr., total temperature. Several manufacturers displayed large valves equipped with the Dean system of electrical control in operation at the show.

There were a large group of manufacturers showing steam traps, damper regulators, steam and water regulators, air regulators, injectors and ejectors, inspirators, oil separators, and grease extractors. One particularly interesting exhibit of steam traps was a glass model of a trap working under steam pressure. The outfit consisted of an electrically heated boiler with pump so arranged that water can be supplied to the reservoir which the trap drains.

The importance of high-grade packings and gaskets for high pressure steam as well as for the great variety of liquids and gases used in industrial and chemical plants attracted attention to the section of the show devoted to these materials.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

LEAKING TRAPS

A large public building is equipped with two separate heating systems. One is located under the windows with 6,562 square feet of direct radiation. Steam is supplied to the system through a pressure reducing valve at 3 lb. per sq. in. The other is a hot air system using motor driven fans. The air is heated by eight stacks of heating coils with a total heating surface of 2,712 square feet. Air is drawn from the outside through gratings in the sidewalk.

Steam is supplied to the coils at 4-5 lb. per sq. in. pressure after passing through a reducing valve. The 4 inch steam line is 260 feet long and carries steam at 70 lb. per sq. in. The average temperature of the air entering the fans is 48 deg. and a temperature of 68 to 70 deg. is maintained on the floors.

Both systems are connected by common returns to vacuum pumps in the boiler room, but when the indirect system is operating a proper vacuum can not be held unless a jet of cold water is fed into the suction line of the pump, due to the high temperature of the returns.

What is the cause of this trouble and could we save fuel by having the pressure reducing valve located at the boiler instead of close to the coils?—A. V. BUCHNAM, Victoria, B. C.

Answer:—The trouble is due to steam leaking from the coils to the returns, in this way tending to keep the return water too hot. Water boils at 212 deg. F., at atmospheric pressure, but as soon as a partial vacuum is produced the boiling point is around 193 deg. F. What is occurring in your returns is probably as follows:

Steam from some source or other is finding its way to the returns and destroying the vacuum. This leakage is no doubt due to defective steam traps on the heating coils. Look to the drip traps on the risers. Repair the present traps if they are defective or replace with a trap that will close tight against steam loss after discharging the condensation.

If, on examination of all the traps, they appear in good shape, it might be advisable, if the trouble still persists, to make an inspection of the pipe lines and look for some by-pass or steam connection that might be allowing steam to short-circuit through to the returns. By-passes are sometimes put on for draining lines or for starting up in a hurry and, as the valves are sometimes not tightly closed, steam keeps leaking back to the returns.

One thing is certain, steam escaping to the returns is the cause of the trouble.

There would be for all practical purposes no difference in the quantity of steam used on the building, whether you carried the 260 feet line at high or low pressure.

The velocity of steam through pipes is confined to certain velocities, which experience has proven to be the most economical both from the point of view of the cost of installation and loss in heat from the steam.

With the low pressure steam of 3 lbs. the temperature is about 222 deg., and with steam at 70 lbs. the temperature is about 316 deg., indicating that with the low pressure steam, due to the lower temperature, the radiation loss would be less; on the other hand the volume of steam with the low pressure (3 lbs.) is about 22 cu. ft. per pound, with 70 lbs. the volume is about 5 cu. ft. per lb. or with the low pressure steam the pipe volume would have to be 4 times that used for the 70 lb. line. This would necessitate a pipe of double the diameter and double the radiating surface.

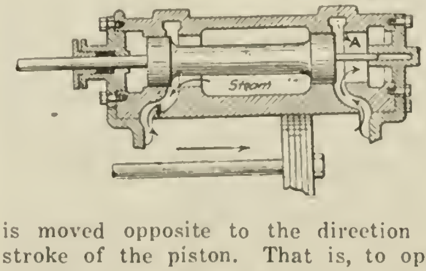
With the low pressure then, the radiation losses, in spite of the lower temperature of the steam, would be greater, to say nothing of the expense of erecting an 8 inch line in place of the present 4 inch line.

INDIRECT PISTON VALVES

What is an indirect piston valve for an engine and why is it so called?

—A. WYLIE

Answer.—An indirect valve is so designated because, for admission of steam at the beginning of a stroke, the valve is moved opposite to the direction of stroke of the piston. That is, to open the steam port the eccentric follows instead of leading the crank.



The figure illustrates an indirect piston valve in which steam is taken beneath the valve while exhaust is taking place at the end A of the valve, thus reversing the method of steam distribution of the ordinary D-slide valve.

SETTING VALVES

In setting a D-slide valve, is it of greater importance to obtain good leads or to equalize the cutoffs of opposite ends?

—W. H.

Answer.—The economy of the engine is not materially affected by a considerable variation of the point of cutoff, but it is desirable to have sufficient lead to fill the steam passages with steam by the time the piston is ready to start out on its stroke, and sometimes also for smoother running to cushion the piston over the centre on engines where there is little compression of the exhaust.

There is a considerable lowering of the pressure when the steam enters the cylinder and comes in contact with surfaces that have previously been cooled by the exhaust of lower temperature, and, if admission at full pressure is delayed, the re-heating of the cylinder with reduction of pressure is extended to the period of admission.

FREEZING TRAPS

I am in a power plant where it is necessary to close off a section of the heating system during the winter, sometimes for a number of days, sometimes for only a night at a time. The traps nearly always freeze up and give no end of trouble, even when the return lines are drained.

Can you suggest a radiating system with a style of trap that can be used for the work that will not freeze up?

The present one is similar to the coil system shown in the September 20 issue of Power House. The returns run horizontally with very little fall.—J. H. STACEY, Winnipeg.

Ans.—You are up against a real problem unless you change present methods of heating the building. The real source of the trouble is caused by the water of condensation from the steam when starting up, not as might be supposed by some water remaining in the traps and freezing as soon as the temperature falls below the freezing point.

Assume the whole system is properly installed with good traps and proper returns. When the steam is turned off with the system hot, enough heat is retained in the metal to dry out any water in the radiators or the traps. The traps then can not freeze up because there is no water to freeze them.

When the heat has been turned off the system, the temperature drops and may be considerably below the freezing point of water (32 deg.).

When the steam is turned on with the

radiators and traps cold, some of it is condensed at once and is cooled by the metal, so that when it reaches the traps its temperature is about at the freezing point.

The result is that the small outlet through the trap immediately becomes frosted over or frozen up, forming a dead end. As there is then no circulation in the pipe leading to the trap and in the trap itself, the only practical method of opening the trap is by applying heat externally.

I do not know of any make of trap which would overcome the troubles when used in a building in which the temperature is allowed to drop below the freezing point; however the following pointers by a prominent heating engineer may be of value to you.

The use of a check valve instead of a steam trap may be of assistance, because of the larger passage for the steam to pass through, a slight amount of frosting will not be so apt to plug the outlet.

Check valves are not as efficient as traps because of the steam which is allowed to pass to the returns with them.

If there is a warm basement under the building, locating the traps in it will prevent freezing.

If possible locate the supply line close to the trap so that the heat given off from the steam in the supply will heat up the trap and thaw it out if it is frozen. In some places where the piping is installed it is probably impossible to change the piping except at considerable expense, in others it may be possible to run the supply next the trap at a trifling expense.

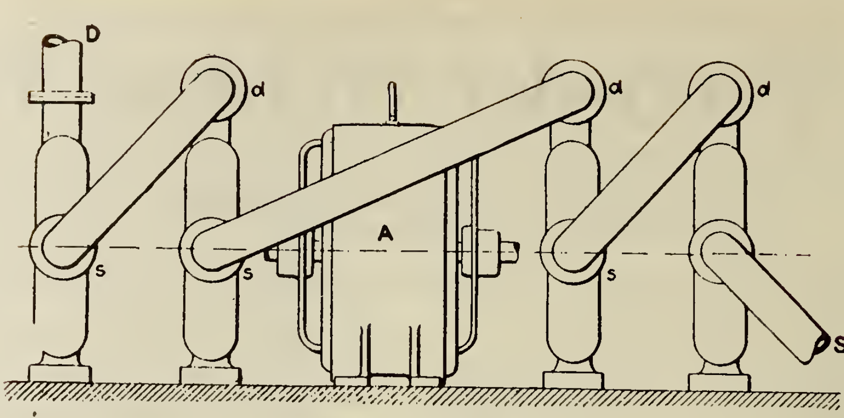
It is best to keep a small amount of steam passing through the system, not necessarily enough to heat the building, but merely sufficient to prevent the returns and the traps from freezing. This last suggestion would apply especially when the heat is turned off at frequent intervals for short periods.

CENTRIFUGALS IN SERIES

For raising water with centrifugal pumps, where a single pump cannot raise the water to a sufficient height, cannot several centrifugals be employed in series? —A. HENDERSON.

Answer:—The required energy may be imparted to the water by means of two or more moderately sized pumps arranged in series of place of a single pump of large diameter running at a high velocity. High lifts frequently have been accomplished in this manner, using a pair of centrifugals driven direct by a double-cylinder steam engine or other motor. The figure is a sketch diagram representing an arrangement of four centrifugals as coupled by a European maker to an electric motor A with all mounted on the same bedplate.

Water received at the main suction S of the first centrifugal is successively delivered by the delivery outlets d and suctions s to the fourth centrifugal with the discharge D. It is understood that a plant of this kind was employed to raise water through a height of more than 150 feet.



Centrifugal Pumps in Series.

SUCTION LIFT

What is the rule for height of suction head or suction lift for pumping water of a given temperature?—C. A. S. E.

Answer:—With a velocity of from 3 to 4 feet per second and a short suction pipe with one bend, water under atmospheric pressure and as warm as about 160 deg. Fahr. will require no suction head, and at 212 deg. Fahr. will require a suction head of 12 ft. For each deg. Fahr. from 160 deg. Fahr. to 212 deg. Fahr. there should be a suction head of 2¾ in.

At 60 deg. Fahr. the suction lift may be as much as 22 ft., and from 160 deg. Fahr. down to 60 deg. Fahr. there may be a suction lift of about 26⅝ in. for each deg. Fahr. of the water below 160 deg. Fahr. If the suction pipe is long, the velocity high, or there are many bends or other obstructions, such as a foot valve, strainer or surface condenser, the losses must be estimated and deducted from the available lift computed by this rule.

WATER IN FUEL OIL

I use fuel oil for firing and have a condition that is giving us trouble. We have underground storage tanks, and there is a percentage of water that will not separate from the oil, but hangs in solution and when agitated by pumping the oil becomes emulsified. How can the condition be overcome?

— A. HEINRICK

Answer.—When water cannot be separated by allowing the oil to stand a reasonable length of time to allow the water to settle to the bottom of the tank, it can be removed by passing the oil through a centrifugal separator on its way to the furnaces.

This method is commonly used for improvement of fuel oils for removal of dirt and water without depending on quiet storage for settling the impurities.

CHECK VALVE LEAKAGE

How can it be determined whether a boiler-feed check valve leaks?—S. M., Toronto.

Answer:—When pump valves and water pistons are not perfectly tight and the feed-stop valve is left open when the pump is not running, the hot boiler water will be forced back to the pump and check valve leakage will be revealed by a higher temperature of the feed pipe near the boiler than when the pump is feeding the boiler.

A surer test of the check-valve leakage is to tightly close all direct supply connections to the check valve. Then with boiler pressure on the discharge side, test for leakage by bleeding any direct supply connection between its stop valve and the inlet side of the check valve.

The Hydro Electric Power Commission, of Ontario, is conducting negotiations for purchasing the plant of the insolvent Georgian Bay Power & Milling Co., Meaford, Ont. This is a result of the January vote of Meaford to adopt the Hydro.

Comments in the Power Plant Field

ELECTRICAL KNOWLEDGE

It is necessary for most stationary engineers to have a certain amount of electrical knowledge, and where one should start to learn this subject seems to be a much-mooted question. Naturally, the information that one desires to obtain is that which concerns the equipment under his charge whether it be generators or motors.

To all, but especially those who are not familiar with electrical apparatus, a study of "Ohm's Law" and its practical application to various problems is interesting and instructive.

Ohm's Law was discovered by and named after the German electrician George Simon Ohm, and is: "The strength of the current varies directly as the electro-motive force and inversely as the resistance." It can be more simply expressed thus:

$E = I \times R$ where
E = Electromotive force or volts.
I = Current or amperes.
R = Resistance or ohms.

Named After Italian

A volt, named after the Italian, Alessandro Volta, is the amount of pressure (electro motive force, E. M. F.) required to force a current of one ampere through a circuit having a resistance of one ohm.

An ampere, named after the Frenchman, Andre Marie Ampere, is the amount of current that an E.M.F. of one volt will send through a circuit having a resistance of one ohm.

The ohm is the unit of electrical resistance. Then if $E = I \times R$, it is apparent that we can change the formula around, also knowing any two factors we can easily find the unknown for $E = I R$, then $I = \frac{E}{R}$ and $R = \frac{E}{I}$.

Finding Electromotive Force

For instance, if we have a circuit with a resistance of 5 ohms, and we desired to send a current of 10 amperes through it, what E. M. F. would be required? $E = I \times R \therefore 10 \times 5 = 50$ volts. If we knew the volts and current and wanted to know the R, i.e., through what R will 110 volts send 11 amperes, $R = \frac{E}{I}$ $\therefore \frac{110}{11} = 10$ ohms.

If we wish to find the I from the following, an electric heater is attached to a circuit of 110 volts, the R of heater is 22 ohms, then $I = \frac{E}{R} \therefore \frac{110}{22} = 5$ amperes.

These are some simple illustrations of Ohm's Law, and it would be worth while for anyone interested to work out several such problems and thereby become familiar with its application.—E. GOLIGHTLY.

SMALL PIPE LINES

There is such a thing as making steam pipe lines too large in spite of the advantages of accompanying low steam velocity and slight pressure loss. The trick is to select pipes of the right size—neither too large nor too small.

The size of a steam pipe is usually based on steam velocity. For saturated steam 6,000 to 8,000 ft. per min. is common practice, while for superheated steam 8,000 to 12,000 ft. is often used. Before going above 8,000 ft. per min., however, one should be certain that the piping and valves are of sufficient size and design so that the pressure drop will not be excessive, so that there will be no wire drawing through valves, and no loud whistling noises. By exercising judgment velocities can sometimes be brought up to 14,000 ft. per min. for large reciprocating engines or steam turbines.

The advantages of small piping are

1—Lower first cost. The pipe weighs less per foot. Thinner pipe can be used to withstand the same pressure. Consequently the initial investment is less.
2—Correspondingly smaller and less expensive fittings.
3—Less surface is exposed to the atmosphere, hence the radiation losses are lower.
4—Less insulation is required because of small surface—sometimes a very important item.
5—The greater friction loss through the small pipe tends to superheat the steam. As a result the steam may reach the engine or turbine, after a long run, in a perfectly dry state. The pressure loss is thus converted over into useful heat energy.

It has been suggested by an engineer and the suggestion seems to have some merit—that in long straight runs of steam pipe large valves be used, with smaller intermediate pipe. In this way the steam velocity through the valves would be low, or "just right," and through the smooth pipe the velocity would be high, or, again, "just right." If any of the readers of Power House have had experience with pipe lines designed in this way the writer would like very much to know whether or not they were successful. —W. F. SCHAPHORST, M.E.

M.D.E.A. Notes

The regular meeting of the Montreal and District Engineers' Association was held on Nov. 23, when, in spite of the inclement weather, there was a large attendance of members.

J. Thompson, of the Dearborn Chemical Co., Toronto, was heartily welcomed as a visitor to the lodge, by President W. Forbes.

An election for the vacancy of treasurer took place and by unanimous vote, W. J. Carmichael, of the Mount Royal Hotel, was chosen for this responsible position.

Mr. Carmichael's elevation to the treasurership is a fitting tribute to his faithful attention to duty whilst holding the office of financial secretary of the C. A. S. E. for a considerable period.

Book Reviews

Hydro-Electric Power Stations. By David B. Rushmore and Eric A. Lof. Published by John Wiley & Sons, Inc., New York, 1923. Cloth 6x9 in.; 830 pages; 437 illustrations; 66 tables. Price, $7.50.

This is the second edition of this book, which has been revised and brought up to date so as to set forth recent practices in hydro-electric power developments. The rapid advances made in recent years in water-power development have led to radical changes in both the hydraulic and electrical parts of the station.

The book is divided into ten chapters and an appendix. Chapter I is a general introduction dealing with the history of water power and electrical development, water powers of the world, classification of developments, etc. Hydrology is the subject of Chapter II and treats of properties of water, rainfall, disposal of rainfall, stream flow and energy of flowing water. In Chapter III the various practices in dam and headworks construction are set forth, with numerous examples of the different types of construction. Water conductors, surge tanks, gates and valves are treated in Chapter IV and in Chapter V storage reservoirs have been given attention. In Chapter VI numerous examples of modern hydro-electric power-house construction are given as well as a discussion on the feature of design and putting the station into service. In Chapter VII hydraulic equipment, turbines, draft tubes, governor pressure regulation and flow meter are the chief subjects considered.

In Chapter VIII there are 400 pages devoted to electrical equipment in the plant, such as generators, exciters, relay protection, switching equipment, transformers, synchronous condensers, automatic regulation, etc.

Tell Economy of Powdered Fuel

H. D. Savage, of Combustion Engineering Corporation, and F. A. Scheffler, of Fuller Engineering Company, Address Metropolitan Section A.S.M.E.

THE drawing power of the subject of powdered coal was demonstrated on Nov. 20, when approximately 500 members of the Metropolitan section of the A.S.M.E. assembled to hear lectures on the subject by H. D. Savage, of the Combustion Engineering Corp., and F. A. Scheffler, of the Fuller Engineering Company.

Mr. Scheffler, who was the first to speak, told of the great activities in the pulverized-coal fields. During the year 1922, fifteen million tons of coal was pulverized in the United States and Canada. The figures for 1923 will be about seventeen and a half million tons.

Mr. Scheffler said that powdered-fuel furnaces were now designed on the basis of 7 to 10 ft. per sec. gas velocity. He understood that a special high-temperature firebrick was soon to be placed on the market at a moderate price. The use of such a brick would permit reducing furnace volume 25 to 35 per cent. The use of powdered coal is as safe as stoker firing, he claimed, if the equipment is properly designed. The distributing systems had been so far perfected that powdered coal could be forced through a pipe line one mile long. He pointed out that in making cost comparisons between stokers and powdered coal, the method of figuring often made the cost differential appear much higher than it really was. For example, there are preparation and handling costs with stokers as well as with pulverized-fuel apparatus.

Shows Operating Costs

He gave figures showing that the operating costs with pulverized coal ranged from 57c per ton for small stations to 43c for those of medium size. The corresponding figures for stoker-fired plants were 38 and 36c, leaving the extra cost of pulverizing 19 to 7c per ton. These figures do not apply to large central stations. The gain in efficiency due to pulverized coal was given as 10 per cent. for large plants and 15 per cent. for small.

In his paper on the same subject Mr. Savage stated that powdered fuel was much better established than many other innovations, such as high pressure, air heaters, bleeder heating etc. Since January, 1923, powdered-coal installations for 1,300,000 sq. ft. of boiler-heating surface had been contracted for. These were for all kinds of coal under all kinds of conditions.

Among advantages claimed for powdered coal were the ability to change the proportion instantly to meet changes in the heating value of the coal; complete oxidation of the sulphur, thus using its heat and preventing clinkers; ability to burn high-ash fuel with efficiency; ability to burn coal otherwise unavailable, thus saving on first cost and on freight.

Unfair Comparisons

As to the first cost of the plant, it was pointed out that it was unfair to make the comparison on the same total boiler-heating surface. The use of powdered coal permitted a considerable reduction in the boiler-heating surface for the same plant capacity. If proper consideration was given to such factors and comparison made between two plants, one independently designed for stokers and the other for powdered coal, the latter would show little, if any, greater first cost.

The operating costs, according to Mr. Savage, were no higher for pulverized coal. A slide was shown giving the operating costs at Lakeside station for the first nine months of 1923. Mr. Savage said the importance of the ash question had been greatly exaggerated. There were never any complaints, he said, from the neighbors. If the ash was there, it was too small to see.

Personals

Fraser S. Keith, M.E.I.C., secretary of the Engineering Institute of Canada, was the speaker at a meeting of the Montreal branch of the Institute Nov. 22. The engineering profession is too crowded to-day, Mr. Keith said. There are some 2,383 engineering students in the engineering school of this country, with 585 graduating this year, and there is not sufficient work going on to employ half of the qualified engineers looking for jobs. To relieve the situation and offset the unfavorable position in the engineering field, Mr. Keith suggested dividing the science course into two groups—one to be a four-year course leading to B.Sc., for industrial and other purposes, and the other a six-year course leading to the degree of Bachelor of Engineering.

O. O. Lefebvre, M.E.I.C., chief engineer of the Quebec Streams Commission, addressed the members of the Ottawa Branch of the Engineering Institute in the Victoria Memorial Museum, Nov. 15. Mr. Lefebvre outlined the construction and operation of storage reservoirs for power development, the financing of such undertakings, and the rates determined. Indicating the value of regulating the flow of rivers especially in their relation to industrial development, he stated that many industries during the low water period in the province could not operate but that those industries served by the storage dams the St. Maurice and St. Francis rivers were not so affected, operating for the full twelve months. Lack of water power thus curtailed production and it was the work of the commission to remedy this situation. Mr. Lefebvre announced that the Quebec Streams Commission were now investigating storage possibilities in the Gatineau river, with a view to the development of two power projects.

Dr. Charles Camsell, chairman of the Canadian Fuel Board, has just arrived in Ottawa after two and a half months in England and other parts of Europe. Dr. Camsell attended the economic conference as a delegate from Canada and devoted considerable time to investigating the advance made in Europe in the scientific utilization of coal.

W. T. BRICKENDEN, B A., Sc., A S M.E.

The Under-Feed Stoker Company of Canada, announce the following change in their personnel: W. T. Brickenden, B.A. Sc. (Honors) A.S.M.E., has been appointed chief engineer for the company; vice, D. F. Grahame, who has been transferrerd to the head office of the Sanford Riley Stoker Company of Worcester, Mass.

Mr. Brickenden, a graduate of Toronto University, Faculty of Applied Science-Mechanical Engineering, has been with the company as assistant to chief engineer since 1920 and has been engaged in research and installation work during the ensuing period.

Trade Catalogs

The R. H. Beaumont Co. of Philadelphia have published a 250-page catalog describing coal and ash handling systems for boiler houses.

The catalog is divided into four sections, the first dealing with central coal and ash handling systems, the skip hoist for coal and the skip hoist for ashes; the second section describes the coal weight lorry; section 3, the cable drag scraper and the last section, steel suspension bunkers, steel circular bunkers, double roll coal crushers, coal and ash gates and general engineering data.

The booklet is well illustrated and contains many useful suggestions and valuable data for the engineer on the handling and storage of coal and ashes. The Combustion Engineering Corporation of Toronto are the Canadian agents for The Beaumont Co.

The new 28-page Catalogue No. 1,400, just received from the American Schaeffer & Budenberg Corp. of Brooklyn, N.Y., is a complete treatise on pop, safety and relief valves and every engineer interested in the subject should procure a copy.

Of particular interest is the Model "J" high capacity pop safety valve, which is a new achievement of the company. It is a well-designed valve and, while universal in its application, is particularly suited for water tube boiler service where saturated steam not exceeding 250 lbs. pressure is encountered. Its exterior design is compact and well rounded, insuring maximum strength at all points.

The De Laval flexible coupling is described in a 12-page pamphlet issued by the De Laval Steam Turbine Company, of Trenton, N. J. This coupling, which has been developed for turbines or other motors geared or direct coupled to pumps, generators, and similar machinery, consists of two opposed flanges mounted on the driving and driven shafts respectively.

One flange carries bolts or pins which enter holes bored in the opposing flange, but not coming into metallic contact with the latter, as the driving force is transmitted through steel-lined molded rubber bushings slipped over the pins. The rubber supplies the flexibility required to take care of inevitable slight misalignment, does not require lubrication, absorbs shocks and is long lived and reliable.

There is no constraint upon independent endwise motion of the shafts, and one shaft can be removed without disturbing the other. The peripheries of the flanges are ground to true cylinders and the faces to true planes to facilitate lining up. All parts are made to limit gages and all similar parts are interchangeable.

A little booklet on modern steam pipe insulation has been issued by the Armstrong Cork and Insulating Company in which attention is directed to the development of a new material for insulating purposes.

The new covering is termed by the makers Nonpareil High Pressure Covering, and has for its basic material diatomaceous earth, (kieselguhr), for which the producers claim greatly improved efficiency over the materials generally in use for this purpose.

Diatomaceous earth is a marine deposit composed entirely of the minute shells of aquatic organisms called diatoms. These shells are practically pure silica, from which all organic matter has been dissolved, and they are hollow and so small as to be visible only when highly magnified.

This earth is found in beds often hundreds of feet thick, where age-long deposits of myriads of these tiny shells has created a firm chalk-like white substance. Its microscopic shells are hollow and form a mass of tiny air pockets so small that the air cannot circulate either within or between them, and this it is stated is such a cellular structure as will contain entrapped non-circulating air particles in the manner regarded as most efficient in heat insulation.

Other advantages claimed for this material are that it is almost pure silica, and is, therefore, insoluble in water, and its structure and composition is such that it is capable of withstanding a high degree of heat without breaking down.

Steam turbine plants will be interested in the new Uehling bulletin No. 150. It describes the combined barometer and vacuum recorder, which instrument is, in effect, an automatic log of steam turbine and condenser performance, because it records the absolute back pressure of the turbine continuously, thus showing up instantly any air leakage or other cause of reduced efficiency. This is accomplished by tracing the records of both barometric and vacuum changes on the same chart. The absolute back pressure is read directly from the vacuum record by using the barometric record as the base line.

When the vacuum fluctuations parallel the barometric fluctuations on the chart, conditions are normal, but a divergence of the two records warns the operator that immediate attention is required. The working range of the chart is expanded and hence remarkably legible. The instrument operates on the mercury column principle, consequently stays in calibration permanently, because there are no moving parts to get out of adjustment.

Copies of this bulletin may be obtained from the Uehling Instrument Co., 473 Getty Ave., Paterson, N. J.

The Republic Draft Indicator and Recorder, for which the Dominion Flow Meter Co., of Toronto, is the Canadian agent, employs a more or less novel principle in securing accuracy, according to new literature just published this week.

The operation of the indicator involves a combination of the bell float, the balance, and the plumb weight so designed as to indicate on a dial an absolute pressure independent of the level of the liquid medium. Heretofore, the bell float, sealed with liquid to form a gas holder, has been commonly used for the purpose of indicating low negative pressures or furnace drafts, and a balance must be obtained at a given level of the liquid to correspond with the zero reading of the pointer on the dial of the instrument, which level must be maintained at all times for true draft indications to be shown.

In the construction of the Republic draft indicator, the acting force of the pressure difference is resisted by a positive weight acting on a balance and not dependent on the buoyancy of the material comprising the bell.

The relationship of the angles and weights and the gear ratio is such that the hand moves one-tenth of an inch for each 1-100 of an inch of draft. The scale can consequently be read accurately to a fraction of 1-100 of an inch of water throughout its entire range of zero to minus two inches of water.

Attention is also directed in a new pamphlet to the Republic R.B. boiler meter, handled by the same company. These meters are made for two classes of plants, one using single boilers of less than 100 horsepower and the other plants employing a large number of smaller units, gradually being replaced by larger ones. To these plants it is essential that the fireman be provided with a record that will enable him to obtain the maximum efficiency from the small boilers, and the Republic R. B. meter, as its chief function, indicates to the fireman the load carried on each boiler.

The Wright-Austin Co., Detroit, have issued a booklet on boiler trimmings describing safety alarm water columns for high and low water, water gauges and try cocks, automatic pump governors and automatic boiler feed water regulators.

In the automatic alarm for high and low water, a round copper float idles on the water, two baskets are fitted inside the column, operating a valve which allows steam to blow a small whistle.

When the water in the boiler lowers sufficiently, the weight of the float on the bottom basket opens the whistle for the low water alarm. Should the boiler become too full of water the float is raised up against the top basket, its buoyancy operating the same whistle valve as for the high water alarm.

The advantages claimed for the alarm are: Prevents burning of boiler parts from low water, eliminates danger of water being carried over with the steam in case of high water, and the maintaining of the proper water level at all times, resulting in a saving of fuel.

Progress in New Power Equipment

AMMONIA COMPRESSORS

A NEW line of Canadian-built ammonia compressors in sizes of 2.5 to 42 tons has been placed on the market by the Canadian Ingersoll-Rand Co., 260 St. James St., Montreal.

These small ammonia compressors embody all of the features responsible for the success of Ingersoll-Rand air and gas compressors which have been on the market for over fifty years.

These features, including Ingersoll-Rand plate valves for ammonia inlet and discharge, exceptionally large valve and port areas, enclosed frame construction, with automatic lubrication, etc., enable the users of small ammonia compressors to obtain efficiencies only heretofore attained by large plants.

The light, high speed, automatic action of the valves, improved cylinder construction, and the well protected, properly lubricated driving ends, permit higher speeds with resultant increase in tonnage per horsepower, and per foot of floor space occupied.

An Advance in Design

These new machines are of the enclosed, horizontal, straight-line, centre-crank type, with single-stage, double-acting ammonia cylinders. The design of the frame, crank-shaft, crosshead, and other running parts, is identical with that of the small air and gas compressors and vacuum pumps manufactured by the Canadian Ingersoll-Rand Company. The construction and valving of the ammonia cylinders represent a noteworthy advance in ammonia compressor design, which is of particular interest to users of machines of up to twenty-five tons of ice, or up to forty tons of refrigeration capacity.

The Class "ERA-1" ammonia compressors are arranged for long belt or short belt drive. The smaller sizes can also be equipped with tight and loose pulleys when desired.

The Class "FRA-1" steam-driven units are equipped with a simple piston valve steam cylinder placed between the ammonia cylinder and frame. The piston valve is of the Ingersoll-Rand balanced type, similar to those used on modern locomotives, and together with the wide-range automatic cut-off governor provides for better steam economy than has hitherto been obtainable from small steam-driven machines. With this valve the valve chest gland is subject to exhaust pressure only. It also permits the use of high pressure superheated steam as well as the low pressures common in the past.

Easy to Operate

Both types of compressors are simple and self-contained, easy to operate, economical and thoroughly reliable.

A few outstanding features of design are:

The heavy one-piece enclosed dust and dirt proof main frame lends rigidity to the compressor and simplifies the foundation and installation. It also prevents waste of oil, insures cleanliness and long lived running parts.

The double-acting ammonia cylinder is of cast-iron sufficiently heavy for reboring. The cylinder barrel and heads are thoroughly water-jacketed, insuring efficient lubrication and reducing heat of compression.

The plate valves used for both intake and discharge are placed in the cylinder tangent to the bore, so as to obtain minimum clearance. Discharge valves are at the bottom of the cylinder, thus preventing any liquid ammonia from being trapped in the cylinder barrel. All sizes are equipped with a foot-piece supporting the ammonia cylinder. This foot-piece is an integral part of the cylinder and contains the discharge connection. A small cast-iron soleplate under the foot-piece facilitates removal of cylinder when desired.

Ingersoll-Rand plate valves are used on both intake and discharge. These valves are durable, light in weight, automatic and extremely quiet in operation. Large free port and lift openings offer the least possible resistance to intake or discharge of ammonia gas.

The machines are equipped with a special water-jacketed stuffing box, fitted with a special packing made up of a set of high and low pressure France metallic rings separated by a dry gas vent. An oil gland is also provided with this packing, which acts as a seal, while additional soft packing, adjustable by means of a screwed gland, prevents gas and oil leakage. The France metallic packing is of very high quality and has been particularly successful for ammonia work.

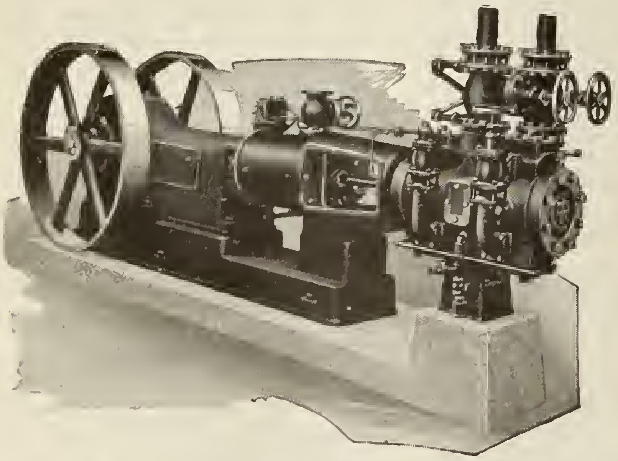
The running parts in all class "ERA" and "FRA" compressors are of very rugged construction. Crankshafts and connecting rods are one-piece drop forgings of special steel. The connecting rods are of the solid-end type with adjustable and renewable boxes. Crossheads are of the bored-guide type with adjustable bored and turned boxes.

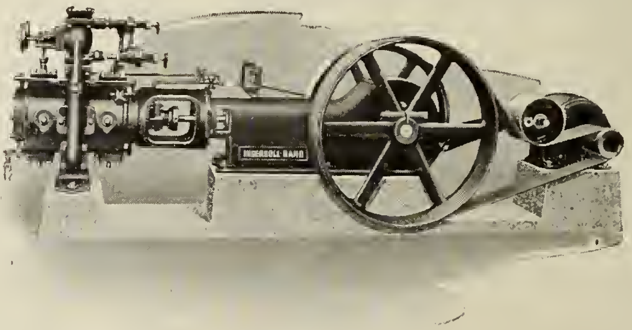
The adjustable, die-cast, removable bearing shells of genuine babbitt metal, insure smooth running and long life, and are easily and cheaply replaced when necessary.

Proportions Lubrication

Main bearings, crank and crosshead pins and crosshead guides have adjustable flood lubrication. Force feed lubrication is used for oiling ammonia cylinder, ammonia stuffing box and steam cylinders. Lubrication is automatically proportioned to the speed of the compressor at all times.

Main ammonia stop valves for both intake and discharge are furnished complete with companion flanges of regular tongue and groove construction. These valves are located next to each other





The photo on the left shows an Ingersoll-Rand Class "ERA-1" straight-line, belt-driven, single stage, double-acting ammonia compressor. On the right is shown an Ingersoll-Rand, class "FRA" ammonia compressor, with short belt motor-drive attachment.

De Laval Oil Purifiers

Insure your Diesels or turbines against damage resulting from keeping inefficient oil in service. They maintain the original characteristics of the oil so that it may be used indefinitely.

No matter whether De Laval Purifiers are considered as a means of saving oil or as a means of protecting engines, they are certain to show greater savings than any other method of purification. The reason is that they effect the removal of impurities by a centrifugal force which is several thousand times greater than the force of gravity—until recently the only moderately successful and economical method of purifying oil.

Write for Bulletin No. 105 which tells how De Laval Oil Purifiers save enough money to pay for themselves.

Safety Plastic METALLIC PACKING

Self-Lubricating
Practically Frictionless

In Cotton Tubes.

Made of an alloy of the finest anti-friction metals, and the best lubricating materials which always remain in the packing; we have records to show that it has been in constant use in many engines, pumps, compressors, expansion joints, valves, etc., for over 12 years, giving consistent satisfaction.

Packing in bulk.

GUARANTED TO LAST THREE YEARS WITHOUT RENEWAL

Let us send you further interesting details also about our "Safety" Superheat Sheet Packing.

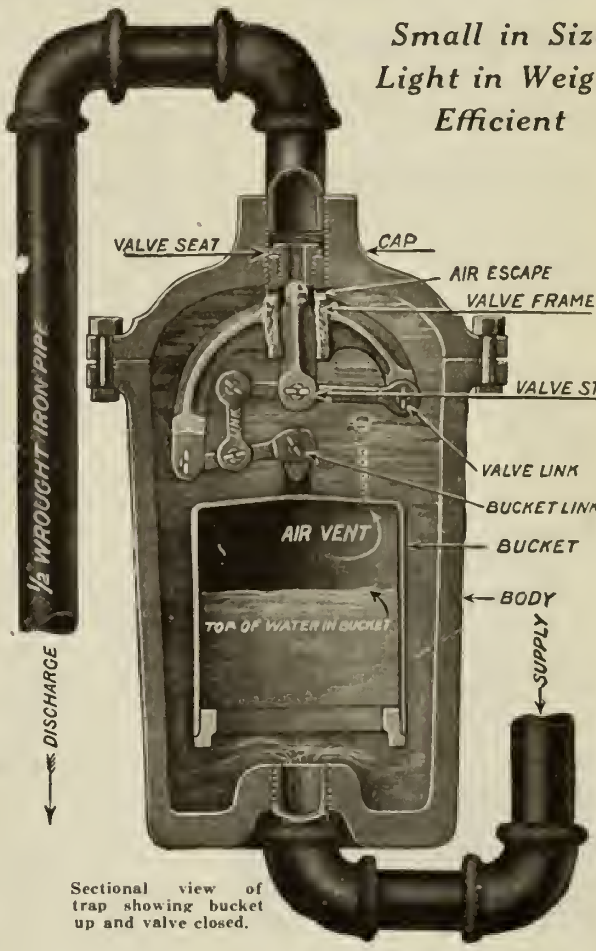
Established 1899 *Agents wanted*

ARMSTRONG STEAM TRAP

Small in Size
Light in Weight
Efficient



Sectional view of trap showing bucket up and valve closed.

Advantages of the Armstrong

Greater Capacity	Than any trap of equal size. Powerful leverage insures full opening of valves.
Self-Scrubbing	Discharge is at the top, so accumulation of oil, sediment, etc., is washed out by high velocity discharge.
Cannot Pass Steam	Closure is positive; steam is trapped in bucket which floats and closes valve.
Action Quick and Positive	Both in closing and opening valve, due to quick passing of point of balance of the bucket.
Non Air-Binding	Port permits positive discharge of air and incondensible gases.
Small Size	Easily supported by any line.
Low Cost	Without sacrificing high quality, because of simplicity.

above the cylinder where they can be conveniently handled.

A special large by-pass valve is provided for complete unloading when starting, so as to prevent excessive current inrush and overloading of the motor.

A spring loaded safety or relief valve is connected to the discharge passage of the cylinder, and the blow-off of this valve is piped back to the cylinder intake.

Pump-out piping is furnished complete with necessary valves and fittings.

Thermometer wells, thermometers and indicator connections are also provided.

The Canadian Ingersoll-Rand Company also announce the publication of bulletin K-214, describing these units. Copies of this bulletin will be sent to any reader on request.

The company also builds at its Sherbrooke plant a complete line of duplex ammonia compressors for steam, belt, oil engine or direct-connected electric motor drive, suitable for larger plants.

A CONDENSATION PUMP

About three to five years ago various makes of electric automatic centrifugal pumps with the usual type of horizontal receiver, elevated six to ten inches above the pump, were placed on the market and found to fill requirements of low first cost, inexpensive operation and dependability.

The difficulty with the original design of these outfits, however, was that the vertical height was such that to flow all condensation by gravity into the receiver it was necessary to place the outfit in a pit, an undesirable location on account of dirt, heat and moisture affecting the electrical equipment. This has now been overcome and eliminated in a new design offered by the Canadian Buffalo Forge Co., Kitchener.

This vertical condensation pump is of the vertical shaft type, submerged in a 40-gallon oblong receiving tank which may be sunk in concrete and given no further thought as the motor is elevated above the floor level as is also the float switch.

All parts of the pump itself are carried or suspended from the cover plate which is conveniently removable, is of comparatively small weight and may be easily lifted off for cleaning or inspection of pump, pit, or float. The float is spherical, seamless copper, ten inches in diameter, carrying a tobin bronze rod passing through gland and stuffing box and actuating the float switch.

Leakage of steam cannot occur around the pump shaft which is fully enclosed between pump casing and cover plate in tight pipe casing. Weight of moving parts are carried on a high grade self-aligning ball bearing, the pump shaft being connected to the motor shaft through a flexible coupling.

The Ever Tyte Piston Ring Division of the Walter A. Zelnicker Supply Co., St. Louis, have issued a pamphlet describing Ever-Tyte and Zelco piston rings.

The rings are of special three-piece construction, and are covered on face with a coating of metal, usually zinc, except when the rings work in ammonia, lead is then used.

The advantages claimed for the ring are: expansion from three points assuring a correct fit in the cylinder, a right-angle interlock which keeps the three members of the ring from spreading and wearing, independent seats in the groove, and the zinc or lead coating on the face wears quickly to a good seat, the metal filling up the pores of the cylinder wall and giving a glazed surface.

Belliss & Morcom, Birmingham, Eng., have issued two pamphlets; one, No. X, describing gas compressors and air pumps, the other, No. 1, emphasizing full economy or the production of cheap power in conjunction with heating and drying by exhaust steam.

The gas compressors are built in various sizes and types with as many as five stages. The pressures for which the compressors are built vary from low to as high as the 3,000 lb. per sq. in. required for compressing air for torpedoes and for compressing gases such as oxygen and acetylene for shipment in steel containers.

The vacuum pumps are made in either the wet or the dry types. In the wet vacuum pump all parts are made of gunmetal with the exception of the valves and the piston rod, which is of stainless steel.

Pamphlet No. 1 contains interesting information on the possibilities of saving in fuel by the utilization of exhaust steam from engines for heating buildings and for process work. Numerous examples are given of actual savings made by manufacturing concerns, which either allowed their exhaust steam to go to waste or used steam solely for heating and purchased their power from a central station.

The pamphlet contains information and tables of interest to engineers on: h.p. from engines per 10,000 lb. of dry steam per hour under various inlet and exhaust pressures, typical lay-out of combined power and heating installation, pass-out engines and turbines, steam pipes, receivers, the flow of saturated steam in pipes, cylinder lubrication, removing oil, heating the feed water, etc.

Announcements

The National Association of Practical & Refrigerating Engineers has sent out the tentative program for its Fourteenth Annual Convention and Exhibition which is to be held in Memphis, Tenn., Dec. 12-15.

Papers of interest to Power House readers are as follows: "Open Brine Refrigerating Systems," by S. C. Bloom; "High-Speed Compressor Valves," by J. H. H. Voss; "Internal-Combustion Engines in Ice and Refrigerating Plants," by A. E. Park; "Evaporating Systems for Refrigerants," by W. F. Davis; "Railway Refrigerator Car Icing Systems," by A. L. Blatti; "Amount of Ammonia Required for Initial Charges," by J. Laichinger; "Cooling Water for Ice Making and Refrigerating Plants," by J. P. Lawlor; "Control of Electrical Equipment in Ice Making and Refrigerating Plants," by H. P. Hill.

"Some Causes and Remedies for

CLASSIFIED ADVERTISEMENTS

TWO CENTS A WORD, including the "Power House" box numbers; minimum charge is $1.00 per insertion, for 50 words or less, set in 6 pt. type. Each figure counts as a word. Display ads., or ads. set in border, are at the card rates.

BUSINESS CHANCES

SMALL BOILER REPAIR BUSINESS FOR SALE—with house property adjoining. No opposition. Located in a large manufacturing city. Reason for selling, owner in ill-health. Apply Box 110, Power House.

POWER PLANT FOR VILLAGE OF TIGNISH About 18 kil. hour capacity 110 to 220 volting alternating current. Apply to John A. Hackett, Box 67, Tignish, P. E. I.

EQUIPMENT FOR SALE

FOR SALE—ONE CANADIAN GENERAL belt driven, direct current generator, 115 to 125 volts, capacity 360 amperes, speed 975 R.P.M's.; also a quantity of used shafting and pulleys. Apply to Box 114, Power House.

SAW MILL MACHINERY FOR PORTABLE medium and heavy mills, band or circular; we build everything for the saw mill from haul-up to sorting table. The Waterous Engine Works, Ltd., Brantford.

TAYLOR SAFE FOR SALE—INSIDE DIMENsions 15" deep, 2 ft. 6" wide, 3 ft. 11½" high. We will accept $225.00 for this safe—a bargain for someone. Apply Box 110, Power House

For Quick Sale

Self-oiling high speed engine, single cylinder 17 in. bore x 16 in. stroke. Engine develops 200 H.P. when running at 235 R.P.M. with 100 lbs. steam pressure. There are two heavy leather belts 18 in. wide. The engine has two fly-wheels, each 78 in. diameter x 18 in. face. Apply **Box 112, Power House.**

PISTON RINGS

EVER-TYTE and ZELCO Piston Rings with Patented Zelco Process Save Gasoline, Oil, Increase Capacity, Prevent Cylinder from Wearing Out of Round, Lessen Carbon; after using, make arrangement with us to sell them; made up to 80-inch; used in Locomotives, Boats, Engines, Compressors, Ice Machines, Autos, Trucks, Tractors, etc.; are looking for distributors with mechanical knowledge; all or part time; real opportunity. Ever-Tyte, St. Louis, Mo.

BOILER LAW

(Continued from page 31)

All agreed with section 9: "No person shall act as an inspector of boilers unless he has passed a satisfactory written examination before a board . . . ."

This section would cancel inspection of boilers by a stationary engineer unless he had passed the examination, and would require all inspectors, whether government or insurance companies, to pass the test.

A penalty is provided for failure to answer pertinent questions of the inspector.

The matter of uniform inspection fee was thoroughly discussed but no action was taken, as it was considered a problem for the department to work out. It is understood that the department is considering a flat inspection fee for the whole province.

The penalty for tampering with safety valves brought forth comment, Mr. Roberts contending that a minimum penalty of $200 was justifiable.

"The penalty for such conduct on the part of the engineer or fireman can not be made too severe."

ENGINEERING LESSONS

(Continued from page 33)

made of the amount of hard scale and soft mud in the boiler, also a sample of each should be saved for the inspector, as these may help him in determining the cause of certain weakening, etc., in the boiler, and he may be able to suggest remedies, such as feed water treatment.

Removing Hard Scale

Hard scale in a boiler may have to be removed by means of a hammer and chisel. In doing this work great care must be taken not to cut or scratch the boiler plate, because corrosion always takes place in a cut or scratch faster than on a flat surface, the deeper the cut the faster the corrosion takes place. Special care should be taken in working around the joints in order not to disturb the condition of the caulking or the rivet heads. At the same time, particular attention must be paid to getting these points thoroughly clean so the inspector can see at a glance the condition of the plates and rivets. Most corrosion and weakening of the plates takes place at the joints. This is probably on account of the original working on the plates; punching, drilling and caulking at these points, which has made these parts more susceptible to corrosion, as pointed out above.

As a rule it is better to remove as much of the scale and dirt as possible by means of scrapers before resorting to the hammer and chisel, which should only be used in the most obstinate cases. The scale can be removed from the tubes by any of the tools on the market for this purpose.

Naturally, all the dirt should be removed from the inside of the boiler, and the inside left as nearly dry as possible for the inspector.

Extraordinary BARGAINS

Steam Engines

1 Goldie & McCulloch heavy duty, cross compound, latest type Corliss condensing engine with rope drive, line shaft pulley and idlers complete, equipped with Dean condenser. Cylinders are 20"x40"x42" stroke. Water heater included.

1 Robb-Armstrong 11"x14" high speed automatic engine, direct connected to a Westinghouse 70 k.w., 3 phase, 60 cycle, 220 volt generator, complete with exciter and marble control panel.

Also several smaller automatic engines and some air hoists from 4" to 10½".

Chain Blocks

2 15-ton Herbert Morris chain blocks with trolleys.

1 10-ton Herbert Morris chain block with trolley.

Water Tube Boilers

2 250 h.p., 175 lbs. working pressure, government certificate. Everything complete and in first-class condition.

SPECIAL

One Jenny Electric Co. push button control complete, in first-class condition, capacity up to a double width sextuple press. This is a rare bargain. For quick sale.

Get full particulars and remarkably low prices from

Wm. Coates

The B. F. Sturtevant Co. of Boston announce the opening of a new plant at Camden, N.J., for the manufacture of sheet-metal work for the installation of sheet metal fan systems including heating, ventilating, drying, exhaust, and conveying work, as well as guards for machines, pulleys and gears.

In addition a stock of standard equipment such as propeller, monogram and planing mill fans, steel pressure blowers, turbo undergrate blowers, blast gates, etc., will be carried.

WORLD POWER CONFERENCE

In connection with the British Empire Exhibition at Wembley, London, next summer, there will be held during July a World Power Conference, which is being arranged by the British Electrical and Allied Manufacturers' Association.

The object of the conference will be to consider how the industrial and scientific sources of power may be adjusted nationally and internationally.

In response to the invitation for Canadian participation, the Hon. Charles Stewart, Minister of the Interior, sent J. B. Challies, his director of water power, to London to confer with the British authorities with a view to having the Dominion's co-operation made both adequate to Canada's unique achievements in hydro-electric matters, and acceptable to the plans of the British committee.

Miscellaneous

Town council, Brockville, Ont., are receiving prices on gas engines for a hydro-electric station.

Price Bros. & Co., 56 St. Pierre St., Quebec, are in the market for equipment for a hydro-electric power house on the Chicoutimi River.

The Empire State Ice Co., Michigan Central Yards, Windsor, contemplate the installation of three ice making machines, electric motors, special refrigeration equipment and brine pumps for an ice plant to supply refrigerator cars. Estimated cost, $100,000.

The Sisters of Jesus and Mary, Outremont, contemplate removing their mother house to Outremont from Hochelaga.

The International Electric Co., Stewart, B. C., contemplate the construction of a hydro-electric plant. Estimated cost $50,000.

Kerry & Chase, Ltd., Toronto, are preparing plans for the construction of a $50,000 electric sub-station for the Hollinger Consolidated Gold Mines, Timmins, Ont.

Dr. L. W. McKeehan, of the research laboratory of the Western Electric Co., N. Y., spoke Nov. 27, in the Physics building, University of Toronto, on "the electrical and other properties of metals as related to the arrangement of their atoms." The lecture was given under the auspices of the Royal Canadian Institute.

H. D. Savage, of the Combustion Engineering Co., in an address on the subject of fuel before the Toronto branch of the Engineering Institute Nov. 20, declared that if Canada would use "pulverized coal," which increased fuel efficiency 25 per cent., it would be unnecessary to import anthracite from the United States.

Hugh Marriott, of the Institute of Mining and Metallurgy, London, Eng., gave an address Nov. 26, to students of all branches of engineering at McGill University.

The Essex Border Utilities Commission, Windsor, is receiving bids for the construction of a pump house, pipe lines and filtration equipment. Estimated cost $150,000. Engineer, J. C. Smith.

The West Kootenay Power & Light Co., a subsidiary of the Consolidated Mining & Smelting Co., is practically doubling the capacity of its plant at Bonnington Falls, near Nelson, B. C.

The Quebec Provincial Government contemplate the construction of a dam at Calumet on the north branch of the Ottawa River. The work will be supervised by the Running Streams Commission.

The Town Council, Oshawa, is in the market for a 1000 g.p.m., 3 stage centrifugal pump to work against a head of 340 ft., direct connected to a 60 cycle, 550 volt squirrel cage induction motor. W. C. Smith, engineer.

Robert S. Whipple, M.I.E.E.F., Inst. P., managing director of the Cambridge and Paul Instrument Co., of England, was the speaker at a luncheon of the Ottawa branch of the Engineering Institute of Canada, at the Chateau Laurier, Nov. 13. Mr. Whipple, who is an international authority on scientific instruments, emphasized the importance of scientific instruments in all lines of endeavor.

"Inductive co-operation as a practical problem," was the subject of an interesting paper delivered before the Montreal branch of the Engineering Institute of Canada by J. L. Clarke, B. Sc., A.M.E.I.C., at its meeting Nov. 15. Election of officers resulted in the choice of O. O. Lefebvre, M.E.I.C., as chairman for the ensuing year and other officers elected were: Vice-chairman, Lt.-Col. Robert Bickerdike, Jr., D.S.O., M.E.I.C., and J. L. Bushfield, M.E.I.C.; executive committee: Messrs. Wm. C. Adams. M. E. I. C., J. Chambers, M.E.I.C., Prof. C. V. Christie, A.M.E.I.C., Aime Cousineau, A.M.E.I.C., P. S. Gregory, A.M.E. I.C., and F.C. Laberge, A.M.E.I.C.

Forty Members of the sales staff of Nesbitt, Thompson & Co., Montreal, the firm who recently purchased the Ottawa and Hull Power Co. and allied interests, inspected the power plant at the Chaudiere Nov. 19. The Ottawa and Hull Co. are planning another addition to its power plant, but as this power has been contracted for in advance, it will not add anything to the available power for the district. The company has a power plant at Calumet Falls, 50 miles up the river, which is now being developed. Plans provide for three installations which will allow a total of 67,500 horse power. Contract for the initial unit has already been let to Fraser, Brace and Co., and the work is well under way.

PRATT & CADY VALVES

P. & C. Swing Checks are made in the regrinding type and with renewable asbestos, rubber or leather discs. They have a full port opening and may be used in either the vertical or horizontal position.

The Swing Type of check valve was first patented by Pratt & Cady in 1878.

Yarway Double-Tightening Valve in tandem with Yarway Seatless. Described in Booklet B-410.

YARWAY SEATLESS BLOW-OFF VALVES are giving unusual service in the plant of the New Castle Leather Manufacturing Company, of Wilmington, Delaware.

Not One Cent for Repairs Nor a Moment's Trouble

A good record is the usual thing for a Yarway Seatless Blow-Off Valve.

A letter of August 31, 1922, signed by Howard C. Kilmon, Chief Engineer of New Castle Leather Manufacturing Co., of Wilmington, Delaware, states: "We have been using Yarway Seatless Blow-Off Valves on four of our five boilers for more than a year. They have not cost us one cent for repairs nor given us a moment's trouble in any way, and we have never known one of them to leak. We are installing at the present time larger boilers of a different type and Yarway Blow-Off Valves will be used on all of our new boilers."

The average good service—often with no repairs—of from eight to ten years of the Yarway Seatless Blow-Off Valve is made possible by its construction. It withstands the destructive action of mud, grit and sediment under high pressure.

Yarway Seatless Blow-Off Valve (formerly the Simplex). Described in Booklet B-410.

The Yarway Seatless and the Yarway Double-Tightening Valve are fully described in Booklet B-410. We would like to send you a copy.

Use

PLIBRICO

for Repairs, During the Christmas Shut-down.

Power costs show a large increase in fuel consumption, at this season, due to short-circuiting of hot gases, where PLIBRICO is not used as a furnace lining.

Minimize this loss by installing a monolithic jointless furnace lining.

Start the new year right.

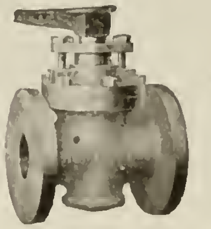
HOMESTEAD

Quarter-Turn Valves

Economy!

A valve to be economical must give dependable, lasting service.

Homesteads open and close easily. The patent balancing parts insure it against sticking. When the Homestead is fully opened, the two surfaces which are depended upon for tightness are in no way affected by the material passing through. The plug cock provides a straight-way opening which is desirable in all sorts of work but particularly so in high pressure service—also in the handling of thick heavy liquids.



Elimination of waste time and leakages quickly pays for all Homestead valves. You would do well to adopt them without delay.

Homestead Valve Mfg. Company
Homestead, Pa.

AIR **The Profit Builder**

In every public building or industrial plant, the installation of modern air handling equipment will increase its profit possibilities. *Your* profits can be increased if you take advantage of American Blower equipment and engineering service along the following lines:

Mechanical Draft
Heating and Ventilating
Generator Cooling
Air Washing
Fans and Blowers
Steam Engines

Bulletins on any of these subjects, embodying the knowledge acquired through forty successful years, will be sent upon request.

This
ANDERSON
Steam Trap

Positively
Prevents
Wasted
Steam

Use it on any Line

WHEREVER there is condensation the Anderson Model "D" Trap will give you economical service. Because it absolutely prevents loss of steam some odd thousands of users are "strong" for this trap. It is the most effective trap because it automatically adjusts itself to any pressure within its capacity. Valves are built of wear-proof, rust-resisting materials. Equipped with a removable strainer which prevents scale, packing, etc., from entering the valve.

Imperial Cutting Oils
Imperial Tempering Oils
Imperial Cordage Oils
Imperial Wool Oils
Imperial Ink Oils
Imperial Greases.

Expensive machinery warrants the protection which Imperial Lubricants assure through correct lubrication of every bearing, journal and other moving part. Plant operation is made more profitable by the standardized use of the right grades of Imperial Lubricants on your different units. When you are confronted with a difficult lubrication job write our nearest branch office for the expert advice and service of our lubrication engineers.

IMPERIAL OIL LIMITED

Boiler Brand

The Simplest and Most Effective

FEED WATER TREATMENT

Silicate of Soda is the base of the majority of Boiler Compounds on the market—often made up under special names.

Boiler Brand is but one of our many grades of Silicate of Soda. It does the work of the most expensive compounds but as the engineer knows just what it is he can adapt it to varying conditions. Why bother with complicated treatments for the removal of boiler scale when the solution is so simple?

"Let a Technical Firm do a Technical Job."

Building a one-piece furnace lining without special forms.

BETSON'S
TRADE MARK
PLASTIC FIRE BRICK

Makes practicable, solid, one-piece furnace linings, including front and back arches, side walls and baffles. It costs but little to install in any make or type of boiler. It saves fuel, annoying shut-downs, costly repairs, and increases the amount of power from the fuel used. It's the ideal material for baffles.

The many uses, methods of installing, how to order, measurement blanks, etc., are given in a booklet which we will gladly send you.

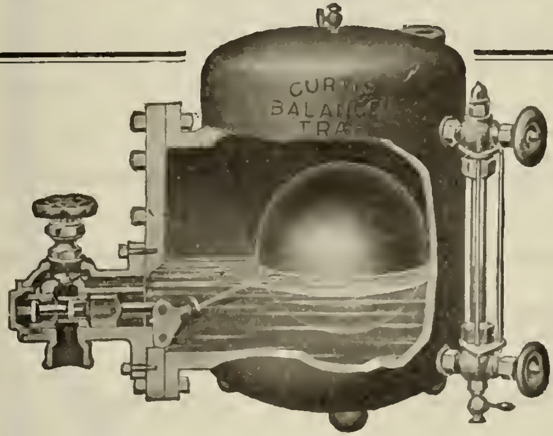
Curtis Engineering Specialties



Five Superior Features of the Curtis Trap

1. A perfectly balanced valve.
2. An absolutely frictionless valve.
3. The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4. The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5. Each trap will operate perfectly on high and low pressures.

Send for descriptive circular of this trap.

Emergencies Prove Its Superiority

It may not be often that the oil film fails in any of your bearings, but the possibility is always present. It is emergencies such as this that test the value of your bearing metals. Magnolia Anti-Friction Metal protects your shafts and bearings from damage in such temporary contingencies. With the lowest frictional coefficient of any known bearing metal—proven by U.S. and foreign government tests—it runs cool with less lubricant and is a safeguard against hot boxes and melting out where lubrication is neglected or may fail for any reason.

Try out a sample Magnolia-lined bearing and test its many advantages for yourself.

Magnolia Metal Company
37-39 Shannon St., Montreal, P.Q.

It's All In the Tanning!

Even the tough back portions of the choicest hides, specially selected by experts, such as used exclusively for **D. K. McLaren's Leather Belting,** would make only **ordinary** belting were it not that every inch is subjected to the **Genuine British Oak Tanning Process**—for many years a closely-guarded secret of British tanners.

The wonderful toughness and flexibility of **D. K. McLaren's Belting** is due, principally, to this tanning process. It gives it greater strength, greater durability and makes it as stretch-proof as it is possible for belting to be. It is this which has made **D. K. McLaren's Leather Belting** an important factor in the reduction of transmission costs.

Every length is stamped with the Oak Leaf — it's worth looking for.

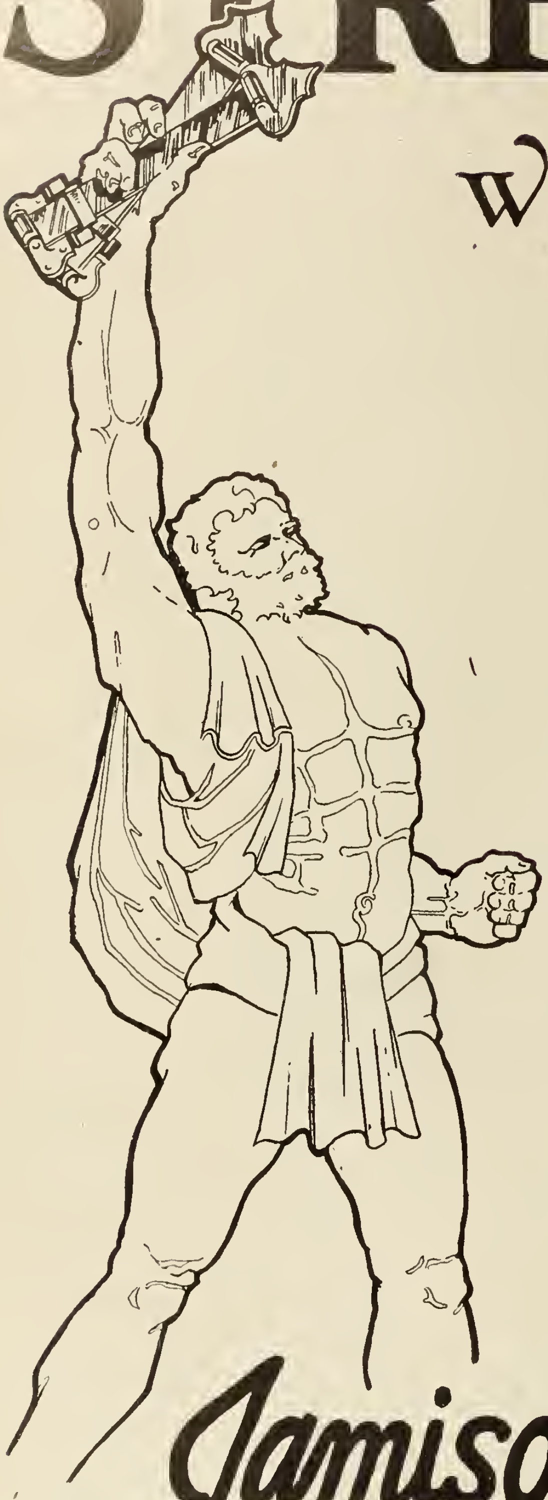
STRENGTH



Where there's weight there's strength

Time tells! Much as the constant drip, drip, drip of water on stone will eventually wear away the surface—so will every-day hard usage make inroads into the efficiency of your cold storage doors.

Ever stop to consider the number of people that pass through your doors each day—going in and out? Ever stop to consider the countless slams, bangs, bumps, and crashes each door has to withstand in every day's work—365 days a year—year in and year out?

The doors of your plant are **important—vitally important!** They must stay "in commission" and serve their purpose without flinching—without taking any trips to the "shop" for repair. For their absence from the line of duty handicaps the efficiency of the plant!

We realize the **importance** that the cold storage door takes in cold storage **plant efficiency**—have realized it for seventeen years, since our very beginning.

By test, Jamison Doors weigh considerably more than other doors. By test, the hardware on Jamison Doors weighs **three times** as **much** as the hardware on **other** doors. The weight PLUS the construction gives the needed strength. Jamison Products are **truly** heavy duty products. And **that's** what you want!

If you care to make a comparative test of these weights, we shall be glad to have you do so—at our expense.

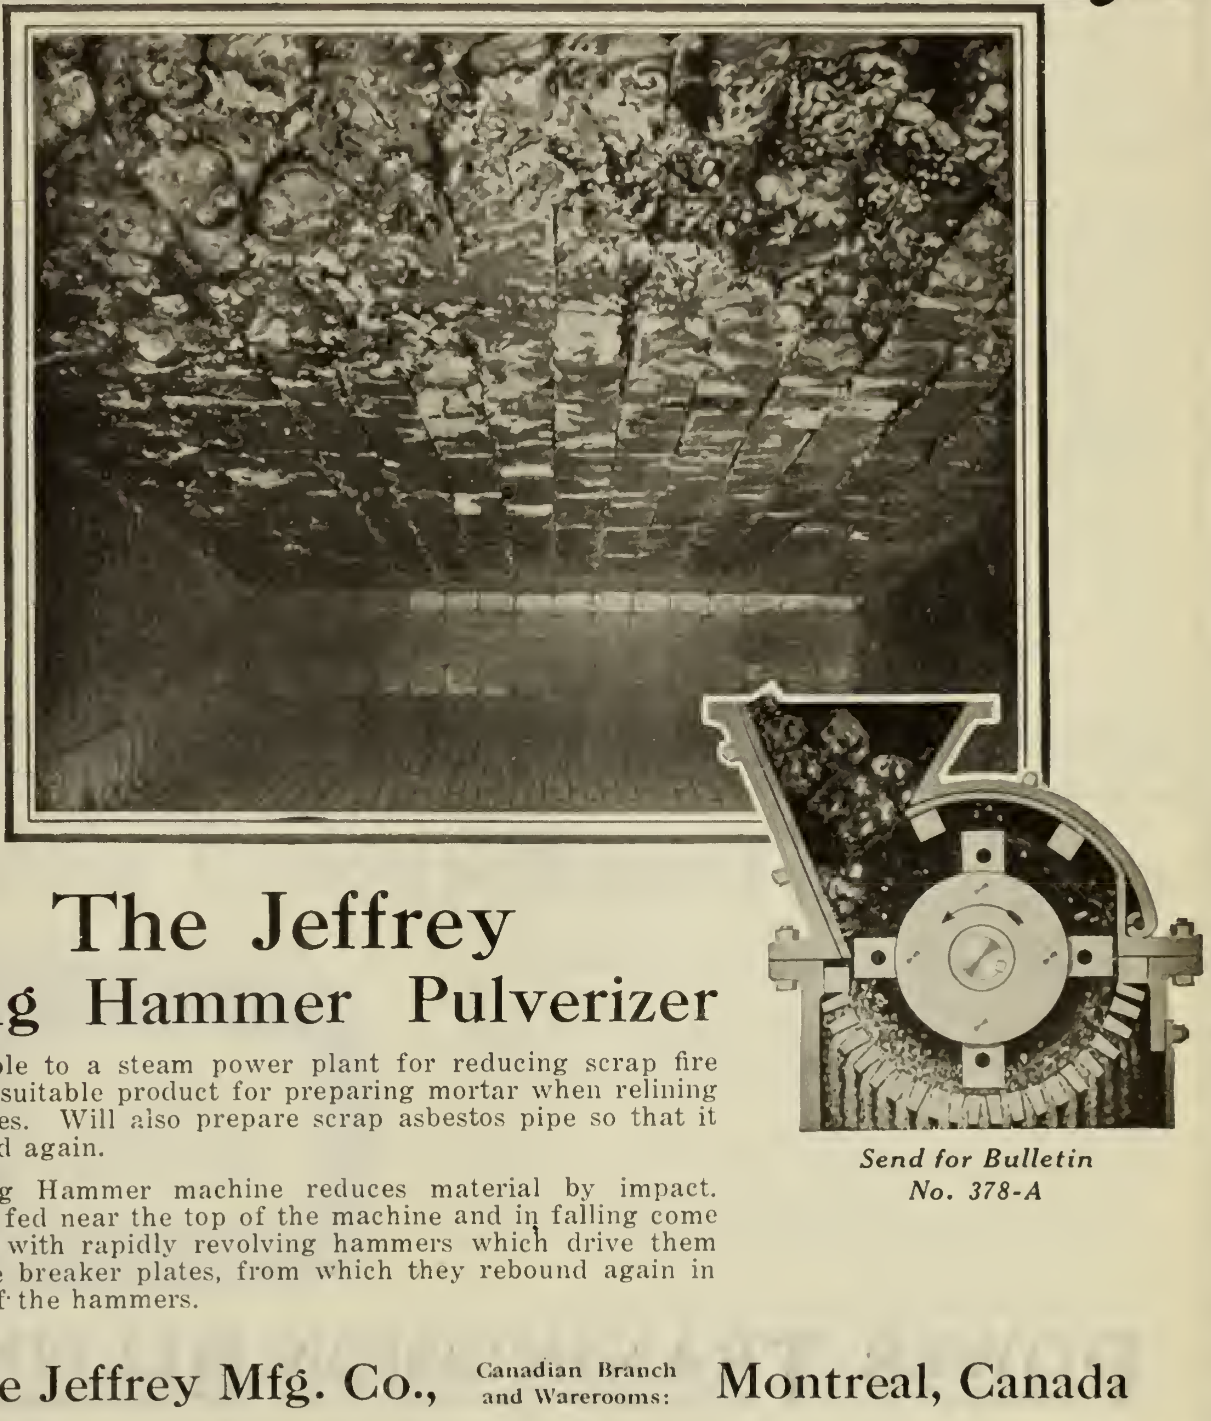
Make Use of Your Old Linings



The Jeffrey
Swing Hammer Pulverizer

is invaluable to a steam power plant for reducing scrap fire brick to a suitable product for preparing mortar when relining the furnaces. Will also prepare scrap asbestos pipe so that it can be used again.

This Swing Hammer machine reduces material by impact. Bricks are fed near the top of the machine and in falling come in contact with rapidly revolving hammers which drive them against the breaker plates, from which they rebound again in the path of the hammers.

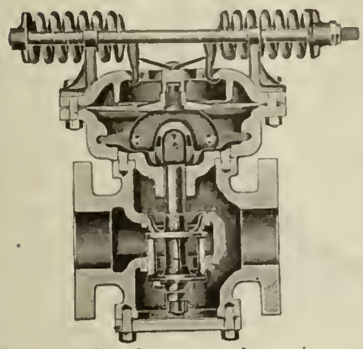
Foster Class "W" Pressure Regulator



The leader for general service on steam, air (certain conditions), and hot water, where delivery pressure is practically constant. It is standard for working pressures of 125 to 250 lbs.

Made in two weights.

For these Reasons—

1. A compensating spring movement exerting a uniform power on the diaphragm, without regard to the opening of the valve.
2. Renewable Seat Rings.
3. Ample Steam Capacity.
4. Drop forged steel stem, levers, toggle levers (case hardened) insuring durability.
5. No small parts to clog.
6. Ease of adjustment and accessibility for repairs.
7. No friction of parts. No dash-pot required. Noiseless in operation.
8. Small movement of diaphragm insuring long life.
9. Absolutely automatic after adjustment is made.
10. Great simplicity of construction and operation.

A. & P. Automatic Hydraulic Vacuum Producer

for creating and maintaining vacuum on steam heating systems in churches, schools, theatres, factories, flats, and residences.

The A & P Vacuum Producer is for removing the air from the heating system and is operated by city water pressure. It is so designed that it completely shuts off the water supply when 3 to 5 inches of vacuum is established and operates again when low vacuum occurs. Maximum capacity with 20-lb. pressure is 2,500 sq. ft. of direct radiation.

Manufactured by

YOUNG PUMP COMPANY OF CANADA

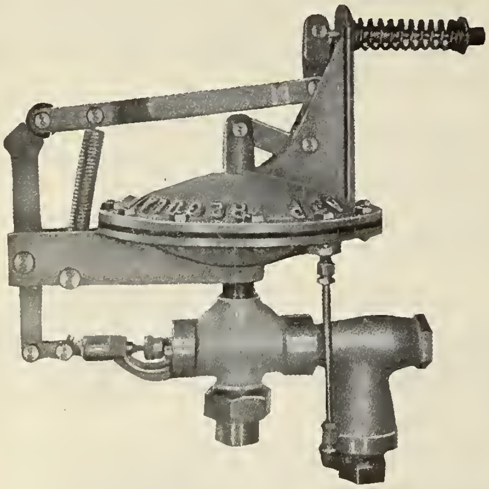
Manufacturers of the Young Centrifugal Vacuum and Boiler Feed Outfit

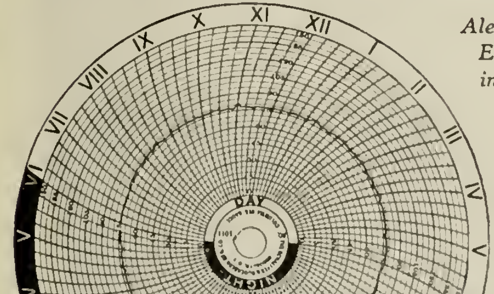


When Enlarging South High School, Youngstown, 60 per cent, they installed a Detroit Underfeed Stoker, and saved 100 Tons of Coal yearly over former practice ~ ~ ~ ~ ~ ~ ~

Naturally you would think that the addition of 42,000 square feet of floor space, to a modern school with its high ceilings and large window area, would inevitably increase very materially the coal consumption. This was not the case however at South High, because they put in a Detroit Underfeed Stoker at the same time that they enlarged the building, with the result that the fuel consumption was cut 100 tons a year.

There is nothing surprising in this record. Every user of Detroit Underfeed Stokers will testify that his savings in fuel have been very much larger than he actually anticipated. The reason—Detroit Underfeed Stokers set new and higher standards in stoker manufacture. Their flexibility, ease of control, and the completeness of combustion effected will surprise and delight you.

Alex S. Allen Engineer in charge



Note the steady, even steam pressure

Repeat orders for Detroit Underfeed Stokers from:

"I Resolve"—

Thinking about the Sarco Temperature Regulator gets you nowhere. The savings effected by this Regulator in the elimination of spoiled goods due to too much or too little heat and by cutting steam consumption, its economy in first cost and maintenance—all these things are lost to you if you simply *read* about them and let it go at that.

Thousands of Sarco Regulators were put into service by men of foresight and initiative who *acted*—men who said to themselves, "I will break away from old-fogy hand regulation and get hooked up with the dependable, money-saving Sarco."

They didn't wait. They didn't defer. They got busy. Judging by some of the letters of praise we receive, you would do well to follow the example of these men.

It is all right to read about the good points of the Sarco, but after you have read, *act!* Say to yourself, "I resolve to install the Sarco Temperature Regulator *now*—without further delay." And then *do* it.

The first step is to write for details of our 30-Day Free Trial Offer, also our interesting booklet J-82

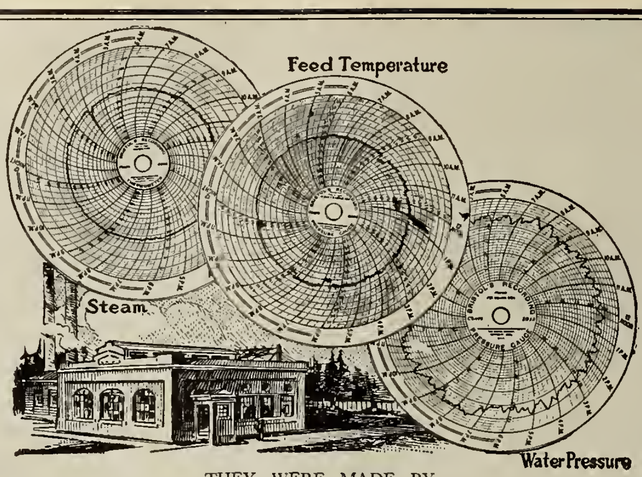
The History of One Day on these Three Charts

At the Winona Public Utility Company Plant.



THEY WERE MADE BY

TRADE MARK
BRISTOL'S
REG.U.S.PAT.OFFICE
RECORDING INSTRUMENTS

and analyzed by the plant owners, as follows:

"The steam chart gives us a record of the steam pressure 24 hours per day. The fireman knows that we have a record of the steam pressure and holds the steam where it should be at all times. He also knows that we have a record of the feed water temperature, and by a glance at the chart he knows if this temperature drops and goes after the trouble, which means a saving of fuel. The water pressure gauge shows the water pressure at all times, which is supplied by a motor driven centrifugal pump operating 24 hours per day. This chart makes a record of any excessive water consumption by a slight drop in the pressure. We have some 2 inch services, which when opened reduce the pressure about 10 lbs. You will also note at 12:30 noon a fire broke out and the fire pump was put on the lines for about 20 minutes which raised the pressure to about 115 lbs. From 9 o'clock at night to 4 o'clock in the morning you will note the chart to show an almost straight line as very little water is used this time of night."

Smith, Hinchman & Grylls, Consulting Engineers, Detroit.

More Steam at Lower Operating Cost

THE PROBLEM.

At the plant of Hiram Walker & Sons, Ltd., Walkerville, Ontario, more steam was required. Their boiler room contained 10—125 H.P. boilers. These boilers were economically fired but the plant layout in general was inefficient.

THE SOLUTION.

They replaced these *10* boilers with *3* of 487 H. P., fired by Riley Stokers which now gives them ample steam capacity. Although the normal boiler H.P. is increased but little the *actual* capacity is about three times greater because the Riley Stokers will operate the boilers up to 250% of rating or more. *When the above picture was taken two of the boilers were making 200% of rating.*

THE RESULT.

Greatly increased capacity with a *reduction in operating expenses.* The improved power plant layout with automatic coal and ash handling equipment and Riley stokered boilers has made possible a reduction in labor from 8 men to 2 men per shift. This saving in labor alone amounts to nearly $100 per day.

Find out what the Riley can do for you. Ask for the catalog.

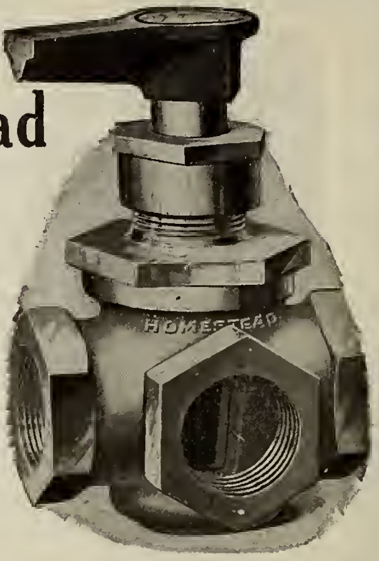
Quarter-Turn Valves
For Quick Opening and Quick Closing



Three-Way Valve.

You want a quick-opening valve, you want a quick-closing valve—then you should adopt Homestead Quarter Turn Valves. They are in addition always tight-closing, and provide an "unobstructed" flow. Homestead Valves are furnished in straightway, three-way, four-way and angle patterns. They are equally adapted for steam, water, air, gas, heavy, gritty fluids and any other power or industrial plant service. Used in thousands of plants in place of globe and gate valves. Order a few to-day.

HOMESTEAD VALVE MFG. CO.
HOMESTEAD, PA.
New York Office: 247 LAFAYETTE STREET

A Jointless Gastight Furnace Lining

The resistance of a furnace or firebox lining is weakest at the exposed edges of the brick, and may be remedied only in one of two ways: first, by setting the brick in Sternson No. 30 High Temperature Cement, or, secondly, by eliminating all edges and building a one-piece lining with

STERNSON NO. 40 MONOLITH

There can be no cracks where Sternson No. 40 Monolith is used. It withstands over 3,000 deg. F. and is not only more satisfactory and economical in operation, but is actually lower in cost than the old way of firebrick and mortar.

It is invaluable for repair work and is often used on the side wall without drawing the fire.

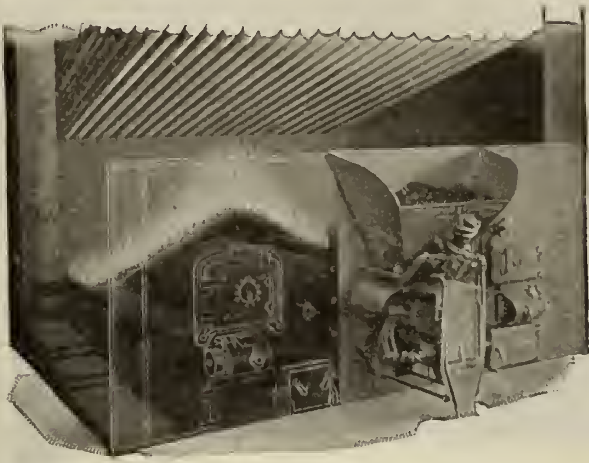
Type E Stoker



THIS stoker is of the underfeed, single retort type, with ample front observation doors and side dumps always under observation and control. The ash dumps are operated from the front of the boiler, and the fact that deep ash pits are not required permits the installation of this stoker where excavation is impossible, as the refuse can be removed on the floor line at the front of the stoker. Grate bars are air-cooled and are alternately moving and fixed. The moving bars have a short upward and outward motion which may be regulated according to the requirements of the fuel. The active part of the fire is continuously self-cleaning:

A few special features of the Type E Stoker are:

The entire length of the retort bottom consists of a sliding member carrying the pusher block and the auxiliary pushers, insuring positive and proper feeding of the coal.

No separate drive required; the steam ram is an integral part of the stoker.

The action of the stoker is controlled by the operating valve mounted on the front of the hopper.

Air from the high pressure compartment passes through and cools the fire bars, and is thereafter discharged between the bars, entering the furnace at a temperature that will facilitate proper combustion.

This stoker is simple in design, may be quickly installed and insures high economy, large overload capacity, and continuous operation. It will burn a wide range of bituminous coals and is applicable to boilers from 150 H.P. up. It is the most widely installed stoker of its type in this country, which is possibly the best evidence of its efficiency and reliability.

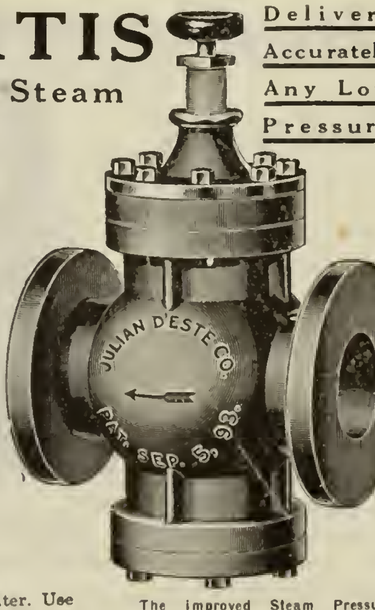
CURTIS
Improved Steam Pressure Regulator

Delivers Accurately Any Low Pressure

A compact, self-contained Regulator suitable for any boiler pressure. It delivers accurately and uniformly any lower pressure from one to within a few pounds of the initial pressure.

It has no levers, weights or projections; no glands or packing; no drip or leak of steam or water. Use it for efficient service on steam-heating apparatus, slashers, jacket kettles, air or water pumps, pulp mills, etc.



The improved Steam Pressure Regulator is a lock valve, very simple and sensitive. Send for descriptive pamphlet.

A Merry Xmas To All

ONE day this week the engineer of one of the Dominion's largest plants sat in his office and talked. All about him were boilers generating steam yet he evidently wasn't thinking of combustion problems or the ever-increasing cost of power when he said:

"It's fun to watch the big eyes of the kiddies when they think about Christmas; to listen to their prattle about Santa; to help them write a letter to the old Saint; to sacrifice a little to make them happy on their biggest day in all the year. Indeed, my wife and I not only plan for our own little ones, but to the extent of our limited means try to make it a Merry Christmas for other youngsters not as fortunate as ours.

"When we see our own boys and girls happy around their tree with the gifts we took so many pains to have just right, we imagine the Christmas spirit covers those other boys and girls too, at the moment, and makes them happy.

"While we think of Christmas as children's day, the children don't get all the joy out of the day. Sometimes the grown-ups, the givers, are even happier in their way. For can anything make one happier than knowing that he has conferred happiness upon others? Can anybody in this world be happier than the father and mother, who, tired after being up all night trimming the tree and arranging the presents, smile over the antics of the youngsters on Christmas morning?"

Yes, this engineer is right when he says Christmas is children's day, but—don't let's forget the old folk who are circling back to the time when Santa Claus seemed so very real — when Christmas morn brought them their heart's desire. The children and the old folk—it's up to the rest of us to make them happy at this time—the one looking forward to life, the other looking backward at life.

Sometimes the world is apt to forget how near to each other the children and the old folk are. Both are so simply satisfied and so easily made happy. Both need love so much and tender care. And while the one openly believes in Santa Claus, the other hugs his memory in secret.

Tuesday is children's day—old children and young children. Let's make it happy for one as the other so that there will be no wistfulness in the eyes of anyone Christmas morn—least of all, in the eyes of the old folk. Their time for giving much is past, but they have come again to that time, when, like the children, there is a wondrous joy in receiving.

Pulverized Coal

ATTENTION is frequently being drawn these days to the use of pulverized coal for the production of steam and while the system is not being used to any great extent in Canada, rapid strides are being made in the United States in the development of satisfactory methods to utilize it.

The problem has been taken up officially by the United States Bureau of Mines, and a federal bulletin has been issued setting forth the nature and uses of pulverized coal.

This bulletin defines pulverized coal, as coal which is so subdivided as to be capable of being burned in suspension when mixed with air.

Practically all coals from lignite to anthracite and coke-breeze have been pulverized and burned successfully, it is claimed, but anthracite and coke-breeze require more energy to pulverize them than do soft coals.

It is recognized, of course, that the cost of preparing the fuel tends to militate against its wider adoption, but it is possible to offset this by the fact that "slack" can be used at a price much lower than that of good coal.

Probably the two greatest difficulties experienced in the use of pulverized coal are, first the storage of the fuel in its pulverized state, and secondly the keeping of the temperature of the furnace within manageable limits.

Pulverized coal forms a highly explosive mixture with air and being very finely divided is easily disturbed by currents of air. To obviate this difficulty, however, the usual practice is to pulverize the coal as required, the pulverizer being a part of the boiler unit.

In one system, which is being widely adopted, the raw coal is conveyed to the bunkers from which it passes through a waste heat gravity dryer, in which the amount of moisture is greatly reduced before it passes to the mills to be pulverized.

From the pulverizer the fuel is exhausted and delivered through cyclone separators to bunkers arranged immediately above the boilers, the function of the separators being to eliminate as far as possible all air from the fuel.

From these bunkers the fuel is delivered through special burners by means of air under pressure in very much the same way as oil fuel, secondary air to complete the combustion being admitted through the furnace walls at suitable points. To keep the combustion chamber walls as cool as possible, these are made hollow and the secondary air serves the double purpose of cooling the furnace walls and assisting the combustion of the fuel, the air being thus preheated before it actually enters the furnace.

Learn a New Wrinkle

EVERY good thing that is done helps the one who does it, and also helps an untold number of others. Read what James E. Noble says: "My present subscription to Power House does not expire until August, 1924. However, I enclose a money order for $2.00 to extend it to August, 1925. I may say that in my estimation Power House is the best journal published as a helpful medium for the engineer who is striving to reach the position of chief. I am a subscriber to practically all the power plant journals printed in the English tongue, so I know what I am talking about.

"While employed as chief engineer at Rockwood Hospital, a government official asked me what journal I would recommend for the use of their stationary engineers, and I did not hesitate to name Power House.

"I did the same thing when chief engineer at the Eastern Hospital, London. Power House is printed so that the man with a common school education can read, understand, and put into practice for the benefit of himself and his employer, its entire contents."

Pumping Water by Compressed Air in Winnipeg

By S. J. MATHEWSON, Jr.

Low Operating Costs and Flexibility of Unit Big Factors in Making Air—Lift System Popular Since Method Was First Introduced About Ten Years Ago

THERE are many industries in which a constant supply of pure, cold water is an economy, if not an absolute necessity. In the city of Winnipeg, the water in the mains has an average temperature of about 70 degrees Fahr. for several months of the year, and for that reason plants requiring a steady flow of clean, cold water for one purpose or another have had to secure their supply from another source—namely, from artesian wells.

At first, the water from these wells was pumped by means of steam-operated, deep-well plunger pumps; but as both the static head and the pumping head vary considerably in different districts in the city, it was very difficult to determine beforehand the correct size of pump that would be needed.

About ten years ago the first air-lift was introduced, and it at once found favor owing to the low operating costs and the flexibility of the unit. The air-lift pumping plants in Winnipeg to-day range all the way from those operated by small vertical compressors to the installations at the Union Stock Yards, where an Ingersoll-Rand 16 and 10 x 14-inch, Type 10, 2-stage compressor is at work, and the St. Boniface water works where three of these units are installed.

By referring to Figure 1 it will be seen that the essential principle involved is very simple, and knowing the physical principles in action, it will not be difficult to understand why the air-lift pump has sometimes been charged with low efficiency which was really due to improper devices and faulty pipe proportions.

Consider Open Well

Consider an open well, or any body of water deep enough, regardless of its volume, or what may enclose it—a pond, lake or river being as good for our purpose as a well. In this source of supply is suspended, or fixed, a vertical pipe for water and a pipe for air. These pipes should be submerged for a certain depth, proportionate to the lift when the pump is at work.

It is clear that the water, being free to enter the lower end of the pipe, will rise to the same height inside the pipe as it stands outside, and in this connection there will be nothing to cause any movement of the water either upward or downward. If we introduce air under pressure through the air pipe into the base of the water pipe, we will have an air lift pump, and the principle of operation, briefly described, is as follows:

The energy operating the air lift is that energy in a volume of compressed air released in a fluid column in the form of bubbles at, or near the end of the submerged portion of the discharge pipe. And the driving force, causing the pump to operate continuously, is the unbalanced hydrostatic pressure in the discharge pipe resulting from a mixed column of water and bubbles of air of less specific gravity than the outside opposed column of unmodified water.

Power Loss Negligible

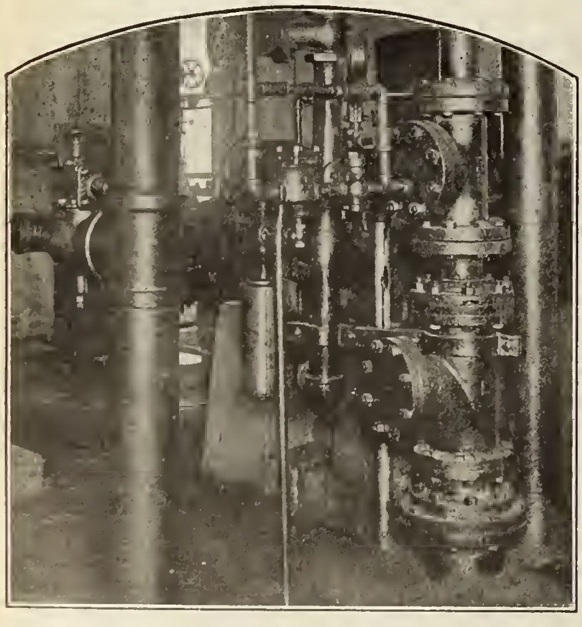
The supply is limited only by the amount available in the subterranean sources. Additional wells may be drilled or the old wells drilled deeper, without the necessity for either deep and expensive pits or concrete linings. The negligible loss in power through air transportation permits the central station to serve wells efficiently even though they are located a mile away from the central station.

Plantations, railway water stations, irrigation projects, large estates and stock farms are using the air lift because of the simplicity of its operation.

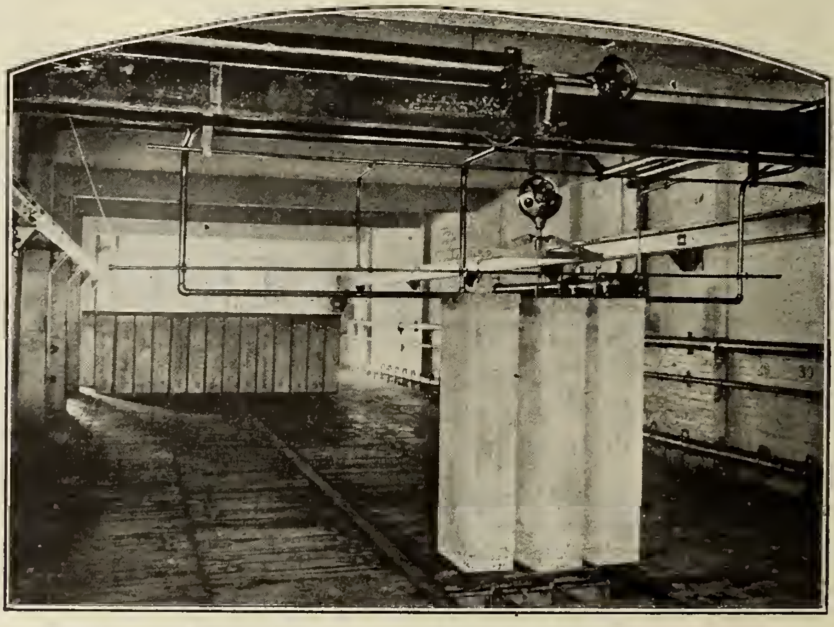
The low maintenance cost and the large capacity of the installations, combined with the flexibility of the entire system, are features which have earned recognition by many industries. Ice and beverage manufacturers, cold storage and packing houses, textile mills, dye works, bleacheries and sewerage installations in increasing numbers are using the air lift for raising water from drilled wells.

For pumping oil wells, dewatering mines and agitating chemicals, the air lift has established its position.

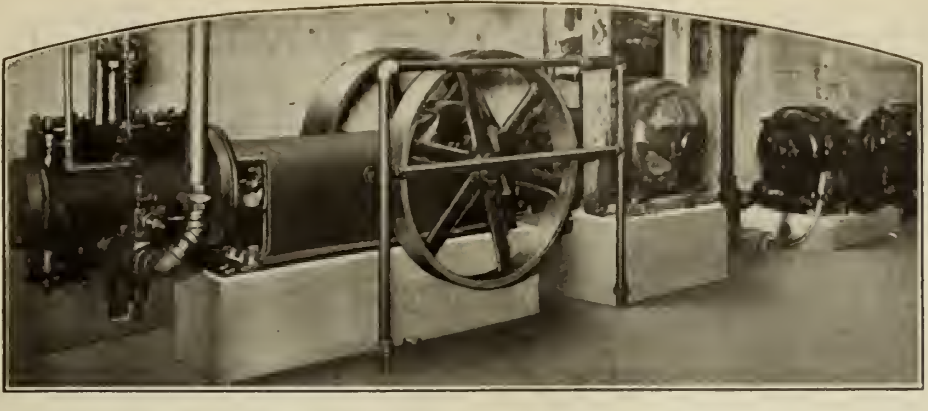
Two of the accompanying illustrations show the very simple arrangement of the



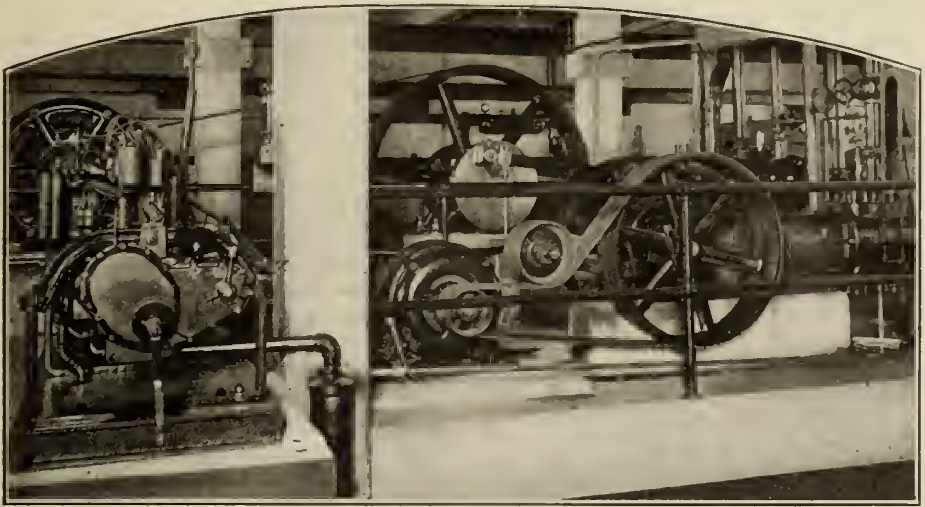
Here are the main features of an air-lift system as installed in the basement of an ice-cream plant.



In addition to using compressed air to operate the hoist in the tank room, the Arctic Ice Company employs this medium to pump water from an Artesian well and to agitate the water in the ice cans.



The 8x8-inch Class ER-1 compressor, with short-belt drive, which furnishes operative air for pumping water at the plant of the Crescent Creamery Company.



In background, compressor which has been giving good service for twenty years in the plant of the Arctic Ice Company, and is still going strong. In foreground, one of the 8x8-inch EL-1 compressors with emergency automobile engine at left.

Well head, with 90-degree headpiece, showing the simplicity of the outdoor features of the air lift at the Crescent Creamery Company's plant.

air-lift system at the Crescent Creamery Company's ice-cream plant at Wininpeg. This plant was using city water, and when it was decided to supply artesian water, the well had to be drilled outside the building.

Well 350 Feet Deep

This well is 10 inches in diameter and 350 feet deep; and the system consists of an Ingersoll-Rand, class VC air-lift pump with a 4½-inch water discharge pipe and a 1½-inch air pipe; of an 8 x 8-inch ER-1 compressor with short belt drive; of an air receiver, and of a Cameron No. 2½ DV pump.

The compressor, the air receiver, and the circulating pump were placed in a convenient corner in the basement of the building, and the air was piped out through a window to the well. The water, in turn, was piped from the well to a large surge-tank in the basement, from where it was distributed throughout the plant by the circulating pump.

It should be obvious that with this system of pumping there is nothing to wear out or to get out of order outside the building, and that it is not necessary to erect a shelter over the well. This is clearly shown in one of the illustrations. The total cost of this pumping plant, including the drilling, the well casing, and the installation of the machinery, was approximately $5,000. Allowing for operating costs, depreciation, interest on the investment, etc., the unit is effecting an annual saving of about $2,500; and, in addition the capacity of the plant has been increased about 15 per cent.

A Simple Adaptation

Another simple adaptation of the air-lift system is that employed by the Arctic Ice Company at their new artificial-ice plant at Winnipeg. Here the well was dug before the buildings were erected. This well is 8 inches in diameter and about 350 feet deep; and the water standpipe is carried straight up about 40 feet to the roof of the structure, where a small tank is placed. The demand for water is so constant that no storage is required, and the tank really serves only to separate the air from the water. The water flows from the tank through the plant by gravity.

This establishment is a striking example of how economy in air consumption can be effected by the application of proper engineering principles. When first put in operation, the ice plant required a compressor with a piston displacement of almost 500 cubic feet. Subsequently, the equipment was carefully gone over, with the result that the changes made brought about a saving of almost 50 per cent. in the consumption of air.

The economies were effected in two ways: first, all the air lines were checked up and, wherever possible, 90-degree elbows were removed, and, where a change of direction was necessary, long sweep bends were substituted for elbows; and, secondly, it was decided that the piping of the air-lift pumping system—that had been installed with a view to taking care of future requirements—

Selecting the Steam Engine in the Power Plant

*By CHARLES L. HUBBARD

Outstanding Features of the Different Types of Reciprocating Engines Must be Kept in Mind if an Intelligent Choice of the Power Unit is to be Made

WHILE the detailed construction of an engine is beyond the scope of the present article, there are certain parts, such as the valves and governing mechanism, which have an important bearing upon the classification of engines and their selection for different operating conditions.

First, take valves. The different forms of valves most commonly used at the present time are the plain slide valve of both the flat and piston type; the releasing and non-releasing Corliss valve; and the poppet valve used in connection with the "uniflow" engine.

A section through the cylinder and steam chest of a slide-valve engine is shown in Fig. 1. The valve consists of a flat plate with openings corresponding to the port openings to the cylinder.

It is rendered practically frictionless by means of a "pressure plate," shown directly above it, and so arranged as to allow the steam to act on both sides of the valve, thus balancing it and eliminating the excessive pressure and wear which would otherwise take place. The balancing feature is one which should always be looked into when selecting an engine of this type.

Another method of securing the same result is by the use of a slide valve of cylindrical form, which is balanced by equal steam pressures acting upon practically all parts, when in operation. The only exception to this is the varying pressure in the ports, when covered by the valve, a condition which calls for special construction in order to avoid leakage around the end section of the valve.

In order to reduce the effect of inertia, the length of travel is often reduced by making the valve doubleported. With this arrangement the same area of port opening is obtained by one-half the movement, other conditions being equal. In Fig. 2 is shown a piston valve of modern design.

The Corliss Type

The four-valve arrangement, with rotary valves of the Corliss type (see Fig. 3) is generally used when higher steam economy is desired. As the admission and exhaust-valves are operated independently, in most cases this design allows of a better timing of the different events of the stroke, such as admission, cut-off, release, compression, and so on, and makes it possible to secure more work per pound of steam than is possible with a single valve.

Furthermore, the quick action of the valves, especially at the point of cut-off, adds materially to the economy of the engine by preventing wire-drawing and loss of pressure.

Limits Condensation

This type of valve also makes it possible to reduce the clearance spaces, and limits cylinder condensation to some extent, because the live steam and exhaust steam pass through different ports, thus reducing the temperature range of the metal surrounding the supply passage during admission.

When both steam and exhaust valves are operated by means of the same eccentric and wrist-plate, the maximum cut-off obtainable is approximately ⅜ stroke, which limits the overload capacity to about 25 per cent. on a basis of ¼ cut-off for normal load. By using separate eccentrics for steam and exhaust valves overloads of 50 per cent. may be carried.

Corliss valves are operated by two forms of gear, the releasing and non-releasing or positive. In the first case, the steam valves, at the point of cut-off are closed by the suction of dash-pots, while with the positive type they are closed by the direct action of the eccentric, the same as the exhaust valves.

The advantage of the dash-pot is the quicker closing of the valve, but this limits the speed to about 120 r.p.m. For speeds above this, the non-releasing gear is used.

Deciding Normal Load

A steam engine is designed to carry a certain predetermined normal load, which is ordinarily about 70 per cent. of the maximum power which it will develop with the same initial pressure and speed, thus making it possible to carry 50 per cent. overload should occasion require.

The office of the governor is to maintain a practically constant rotative speed through a wide variation of load. In electrical work the variation is the entire range from "no load" to "full load."

While the speed variation should be small in certain kinds of industrial plants, where belt or rope transmission is employed, it is especially important

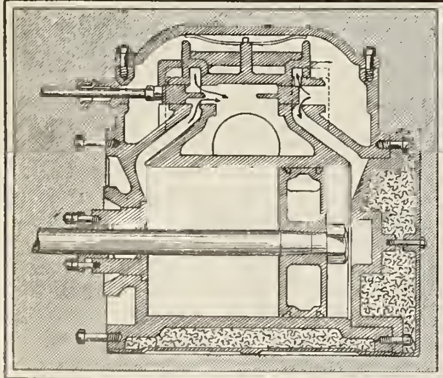

Figure 1: This shows a section through the cylinder and steam chest of a slide-valve engine. Note that the valve is practically frictionless, since steam pressure is allowed to act on both sides.

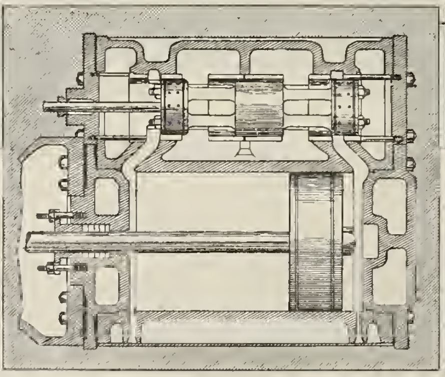

Figure 2: Sometimes small pistons take the place of slide valves as shown in the illustration. By a special design of ports the same size of opening is obtained by one-half the piston travel.

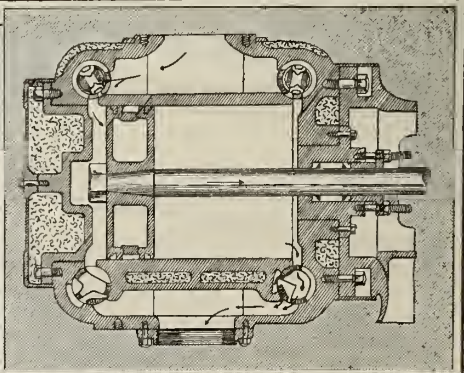

Figure 3: When higher steam economy is desired, the four-valve arrangement with rotary valves is generally used. A somewhat better timing is possible, since exhaust and inlet valves are operated independently.

---

that it be reduced to a minimum where electricity is generated for power work and lighting. This is because the voltage produced by an electric generator is proportional to its rotative speed, so that a change in speed means a change in voltage, a condition especially undesirable in connection with incandescent lighting.

Governor Little Used

The throttling governor, which operates by lowering the initial pressure of the steam supplied to the engine, is not delicate enough for this class of work and is but little used except on steam-driven air compressors, pumps, fan-engines and turbines.

The cut-off governor, which varies the quantity of steam supplied to the cylinder per stroke, is commonly employed on engines used for the generation of power in industrial plants on account of its sensitiveness and close regulation.

A governor of this type is usually attached to the fly-wheel. The variation in cut-off is accomplished by means of a swinging eccentric, the position of the centre of which, with reference to the centre of the crank-shaft, is regulated by movements of the weight or fly-ball. When the load on the engine becomes less than normal, the speed at once increases, and the increase in centrifugal force acting on the weight overcomes the spring tension, causing the arm to swing outward. This, in turn, throws the eccentric toward the centre of the shaft, thus shortening its throw and causing an earlier cut-off.

Use Shaft Governor

Engines equipped with shaft governors of the general type shown, may be made to regulate within 2 to 4 revolutions per minute between no load and full load. In the case of Corliss engines with releasing valve gear, a fly-ball governor, similar to that used for a throttling engine, is commonly used, although it is made to vary the cut-off. Corliss valves of the positive type make use of the shaft governor.

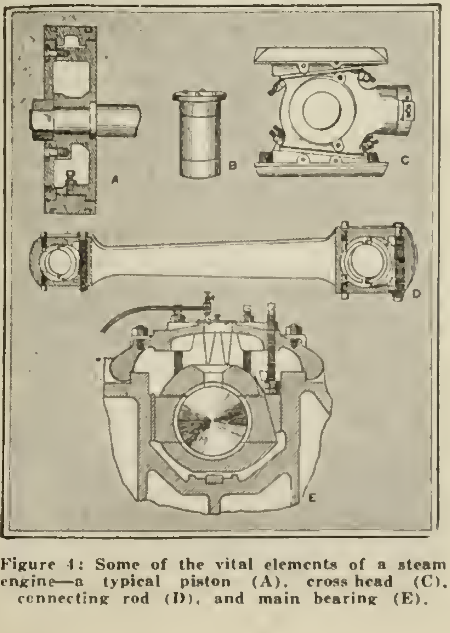

Figure 4: Some of the vital elements of a steam engine—a typical piston (A), cross head (C), connecting rod (D), and main bearing (E).

Without going into details it will be interesting to examine drawings of some of the principle parts of modern engines of the latest design, showing methods employed for adjustment and taking up wear. In Fig. 4 are shown a typical piston, cross head assembly, connecting rod, and main bearing, respectively.

The engines used for the generation of power in shops and factories may be included in six general classes, as follows:

1. High-speed, single-valve, simple engine.
2. High-speed, four-valve, simple engine.
3. Medium-speed, four-valve, simple engine.
4. Low-speed, four-valve, simple engine.
5. Compound engine, and
6. Uniflow engine.

High-speed, single-valve, simple engines are commonly made in sizes up to 100 horse-power or more, and vary in speed from 300 r.p.m. for the smaller sizes, down to 150 r.p.m. for the larger ones. These engines are enclosed, self-oiling and equipped with balanced valve and shaft governor.

Having the fewest parts of any type they require a minimum of attention, and are the least expensive to instal. When floor space is limited or costly, and the exhaust may be utilized for heating and manufacturing a considerable portion of the time, they are suitable for units up to 200 or 250 horse-power, and for larger sizes where practically all of the exhaust can be made use of and where a compact unit is desired.

When more power is required or greater steam economy is necessary, owing to the inability to use all of the exhaust, the four-valve engine should be considered.

Single-valve engines show a fairly constant water-rate from 50 to 125 per cent. of normal load. Below 50 per cent. load the economy falls off rapidly. Steam pressure of 80 to 120 pounds are commonly used, with 3 to 4 expansions under normal working conditions. The water-rate runs from about 28 to 36 pounds per i.h.p. per hour, depending upon the size.

Give Higher Efficiency

The high-speed, four-valve type of engine is equipped with Corliss valves, and non-releasing valve gear, which permits of its being operated at practically the same speed as the single-valve engine. The four valves, however, give a somewhat better steam distribution and higher efficiency, and this type is more often considered for units of 200 horse-power and over where the cost of fuel is high and steam economy of greater importance.

The first cost of an engine of this type is somewhat greater than for the single-valve machine, but considerably less than for the slow-speed Corliss, on account of less weight per horse-power, due to its higher rotative speed.

They are built in sizes up to about 1,000 horse-power, use an initial pressure of 100 to 125 pounds with 3 to 4 expansions, and have a water-rate of 23 to 28 pounds under favorable working conditions.

While the majority of multi-valve engines employ four rotary valves of Corliss type, there are standard makes using both two, and four, slide valves for securing the same results. This type of engine is particularly well adapted for direct connection with electric generators of medium size on account of its high speed, which makes it possible to use a considerably smaller machine for the same electrical output.

Four-Valve Engines

Medium-speed, four-valve engines do not strictly form a class by themselves, but include the smaller sizes of Corliss engines with releasing valve gear, which have a maximum speed up to 120 r.p.m., and the larger sizes of the non-releasing four-valve machines where the maximum speed is around 150 to 175 r.p.m. These employ an initial pressure of 90 to 115 pounds and have a water-rate of 23 to 27 pounds per horse-power, or more, and are especially adapted to industrial plants of fairly large capacity.

A typical engine of this kind is shown which illustrates the massive build of this class of machine.

The classification, "slow-speed, four-valve engines," includes the typical Corliss engine with releasing valve gear, which, until the advent of the perfected steam turbine, represented the highest type of prime mover for large power installations, and for rope driving and belted service in mills and factories is still a favorite type. The speed is limited to 100 to 120 r.p.m., and on account of this low speed, requires a comparatively large floor space and is highest in first cost. The depreciation is less than with the high-speed types, and it will probably maintain its original economy for a longer period than any of the previous machines described.

Needs 80 Pounds Pressure

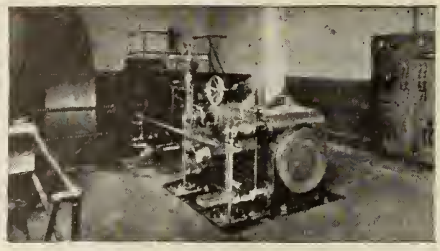
For direct-connected units this engine is not ordinarily chosen for generators of less than 500 to 750 kw., at which point the rotative speed and cost is the same as for the non-releasing four-valve type of engine. This machine is commonly supplied with steam at an initial pressure of 80 to 110 pounds and has a water-rate of 22 to 26 pounds per i.h.p. per hour.

Next come compound engines. The reasons for compounding have been given in a previous article in Power House. All of the different types of simple engines which have been described may be had in compound form, and when used in this way, retain their particular characteristics.

Compound engines are classified as tandem, angle, duplex, and cross-compound, according to their design. The

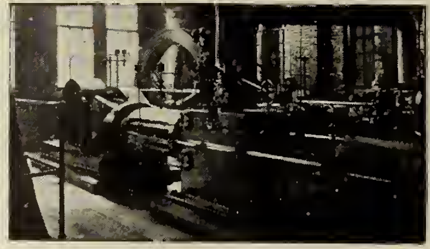
HIGH-SPEED, SINGLE-VALVE SIMPLE ENGINE

Size: Up to 400 h.p.
Speed range: 300 r.p.m. for smaller sizes down to 150 r.p.m. for larger ones.
Water rate: 28 to 36 pounds per i.h.p. per hour. Constant from 50 to 125% of normal load. Below 50% load economy falls off rapidly.
Steam pressure: 80 to 120 pounds with 3 to 4 expansions.
Features: Enclosed; self-oiling; equipped with balanced valve and shaft governor; has fewest parts; requires minimum of attention and is least expensive to instal.



MEDIUM-SPEED FOUR-VALVE SIMPLE ENGINE.

Size: Not strictly a class by itself as regards size for it includes smaller sizes of Corliss engines with releasing valve gear, and larger sizes of non-releasing four-valve machines.
Speed range: 120 to 175 r. p. m.
Water rate: 23 to 27 pounds.
Steam pressure: 90 to 115 pounds.
Features: Adapted to plants of fairly large capacity, have rather massive build.



HIGH SPEED, FOUR-VALVE SIMPLE ENGINE.

Size: 200 to 1,000 h.p.
Speed range: Same as for single-valve engines.
Water rate: 23 to 28 pounds.
Steam pressure: 100 to 125 pounds with 3 to 4 expansions.
Features: Equipped with Corliss valves and non-releasing valve gear: four valves give better steam distribution and higher efficiency; considered where fuel cost is high and steam economy of greater importance; first cost greater than for single-valve machine but less than for slow-speed Corliss.

tandem is the most compact and the cheapest to build, and for these reasons is more widely used than any other. In this case the cylinders are placed end to end, and both pistons attached to the same rod. The remainder of the machine is practically the same as a simple engine.

The angle engine, as the name implies, has the two cylinders placed at right angles; the high-pressure occupies a vertical position and the low-pressure, horizontal. The crank and shaft are common to both cylinders. In the duplex engine one cylinder is placed above the other and both piston rods attached to the same cross-head. A single connecting rod conveys the power to the crank-shaft the same as for a simple engine.

The Cross-Compound

The cross-compound consists of two complete Corliss slow-speed units attached to the same crank-shaft. This type is the most expensive to build and requires the most floor space, but is extensively used in large power installations.

The advantages of the compound engine, as compared with the simple, are a higher ratio of expansion—from 10 to 12 in the non-condensing type; decreased cylinder condensation, due to dividing the temperature range; decreased clearance and leakage losses; equalized crank effort; and increased steam economy, resulting in a saving of 10 to 15 per cent. in the case of non-condensing engines.

Among the disadvantages are increased first cost; greater space requirements; more wear and tear; increased complexity; and greater radiation losses. They are built in all sizes and employ initial pressures of 120 to 160 pounds, depending upon the size and type.

The Uniflow Engine

The latest development in the reciprocating engine for steam, is the uniflow (or unaflow) engine. The economy curve for this type of machine is particularly flat, and for this reason is especially well adapted to the handling of variable loads.

The uniflow principle is employed for the purpose of reducing initial cylinder condensation, which constitutes one of the principal losses in the ordinary form of reciprocating engine. With the uniflow type, steam enters the cylinder at the ends, passing through steam-jacketed heads, and after cut-off and expansion have taken place, is exhausted through ports arranged around the centre of the cylinder which are uncovered by the piston at the end of its stroke.

With the arrangement of cylinder and valves of a condensing engine, the steam flows only in one direction, while in the usual, or counterflow type, it returns on its path at the end of the stroke, and is exhausted at the same end of the cylinder at which it entered.

By this method the cooler expanded steam passes over the cylinder walls and head during 50 to 75 per cent. of the return stroke, thereby cooling them to such an extent that a considerable amount of entering steam at the next stroke is condensed before the point of cut-off is reached.

Multiple Expansion Types

The object of multiple expansion engines, and the use of superheated steam, is to reduce cylinder condensation, but the use of multiple expansion engines complicates the mechanical construction of the engine and increases its cost, while the use of superheated steam results in a certain heat loss and also adds to the cost of installation and operation as well.

The uniflow principle reduces cylinder condensation without superheat, and simplifies the mechanical construction of the engine at the same time. The water-rate varies somewhat with the make and size, but is considerably less than for counterflow engines operating under the same conditions. Published reports of tests run from about 20 to 24 pounds of steam per horse-power per hour for non-condensing engines at full load, down to 13 to 14 for condensing.

From the construction of the uniflow engine it is evident that compression begins as soon as the piston covers the exhaust ports on its return stroke, and therefore continues for about 90 per cent. of its length. With a fairly good vacuum, compression will not rise above initial pressure when running condensing, unless the vacuum for some reason should fail.

Regulating Compression

As fully 90 per cent. of the steam engines in use are operated non-condensing, it is evident that some means must be provided for limiting the compression when starting at, or slightly above, that of the atmosphere. This, in one make of engine, is accomplished by delaying compression through the use of auxiliary exhaust valves placed at that point in the cylinder where it is usual to start compression in a non-condensing, counterflow engine. These valves come into action automatically when the pressure in the exhaust pipe exceeds a predetermined limit.

The condensing engine makes use of a special combination valve which acts as an automatic relief valve when run condensing, and which may also be opened by hand, thus throwing into use additional clearance space when used for non-condensing service.

In some engines the steam is expanded from a small clearance, and by the automatic action of the single sliding valve, is allowed to compress, first into a large chamber, and finally, as the piston nears the end of the stroke, into a small clearance. The steam which has been compressed in the large chamber enters the

LOW SPEED, FOUR VALVE SIMPLE ENGINE.

Size: For direct-connected units this engine not chosen for generators of less than 500 to 750 kw.

Speed range: 100 to 120 r.p.m.

Water rate: 22 to 26 pounds.

Steam pressure: 80 to 110 pounds.

Features: Until advent of steam turbine, represented highest type of prime mover for large power installations. For rope driving and belted service in factories is still a favorite type although highest in first cost.

UNIFLOW ENGINE.

Water rate: 20 to 24 pounds for non-condensing engines at full load down to 13 or 14 pounds for condensing.

Features: Latest development in reciprocating steam engine; well adapted for variable loads; reduced cylinder condensation without superheat; simplified mechanical construction; cost per unit of power is greater than for ordinary single-cylinder, high-speed machine, but less than that of slow-speed multiple expansion engines.

COMPOUND ENGINE

Tandem and angle compound engines: Most compact; cheapest to build; more widely used than others.

Advantages of compound engines: Higher rate of expansion; decreased cylinder condensation; decreased clearance and leakage losses; equalized crank effort; increased steam economy.

Disadvantages of compound engines: Increased first cost; greater space requirements; more wear; increased complexity; greater radiation losses.

cylinder at the opposite end through the automatic action of the valve, and mixing with the expanding steam on the return stroke, expands with it and passes out through the central ports with the exhaust.

The comparative simplicity of a large uniflow engine is shown in the illustration, which also shows the method employed in large units for reducing the friction of the piston. Ordinarily the weight of the piston is supported by the lower half of the cylinder, which is subjected to excessive wear in large machines, and, therefore, makes reboring necessary from time to time, which is an expensive operation.

By extending the piston rod through the rear head, and providing it with a sliding shoe, all pressure is removed from the cylinder walls except that due to the piston packing rings, which is exerted evenly around the entire circumference.

The cost per unit of power for this type of engine is greater than for the ordinary single-cylinder, high-speed machine, but less than that of the slow-speed multiple expansion engines with which it is designed to compete.

The essential features to be considered in the selection of an engine have already been covered, to a considerable extent, in the descriptions given of the different types of machines.

It is evident from what has already been said that there are no hard-and-fast rules to be followed, and that various operating factors must be taken into account as well as first cost and steam economy.

While it is usually assumed that a skilled engineer can be secured for any machine selected, the question of labor actually has a considerable bearing upon the choice of a prime mover. No engine is so good that poor handling, or unfavorable operating conditions, cannot make it an expensive failure. Hence, the availability of an engine room force of sufficient skill should always be taken into account when an engine of complicated construction and high steam economy is under consideration.

The second question to be looked into is somewhat comprehensive, and is usually covered by the term "local conditions." This, in a general way, comprises such considerations as available funds, space for generating machine, cost of fuel of various kinds, quality and quantity of feed water, possible use of exhaust steam, and the value of reliability or cost of shut downs.

All of these points are more or less fixed in any given case, and the task then becomes one of selecting the engine most suitable under the existing conditions, always taking into account plant efficiency rather than engine efficiency alone.

The more important characteristics of the different types of engines have already been given and need not be repeated, except to touch briefly upon the leading features.

Compared with other types of prime movers, the high-speed machines have the advantage of being relatively low priced. Furthermore, the fact that they are comparatively common improves the probability of securing competent attention. The important consideration with this type of engine is the proportion of exhaust steam which can be utilized during each yearly period, under normal conditions.

When all of the exhaust can be employed for useful purposes, the only steam chargeable to power is that which is condensed in the engine cylinder and piping, or leaks past the piston. As this seldom exceeds 25 per cent. of the total amount of steam supplied, it is a comparatively small item and more or less independent of the type of engine. In general, then, where any considerable proportion of the exhaust steam can be utilized, the amount of fuel chargeable to power will be but little less with a high-cost engine than with a high-speed machine of the simplest type.

Each Case Differs

Each case requires individual study in order to determine the comparative costs with engines of the various types.

The items to be considered ordinarily include fixed charges (interest, depreciation, taxes, and insurance; the sum of which is usually assumed as about 15 per cent. of the initial cost), attendance and supplies, fuel and water.

As previously stated, the economy, or fuel per horse-power per hour, may not, under certain conditions, be the determining factor where all things are taken into account, and the plant as a whole—generators, boilers and auxiliaries—must be considered, to make a true comparison.

MERCURY THERMOMETERS

A new method of thermometer tube construction known as the TAG-Hespe Red Reading Column has been developed by the Tagliabue Mfg. Co., Brooklyn. A broad red line shows from the top of the mercury column to the top of the tube. When the mercury rises it covers more of this red line; when the mercury falls a correspondingly greater length of the red line is exposed. The decided contrast between this bright red line and the metallic grey of the mercury brings to the accurate mercury thermometer the easy readability of the red spirit instrument.

TAG-Hespe thermometer glass (tubing) is in every way similar to ordinary lens front thermometer glass except that in TAG-Hespe glass the back of the fine capillary bore (up and down which the mercury travels) is made of bright red glass. This red streak of glass extends all the way from the top of the thermometer down to the bulb.

The red line attracts the eye at first glance and it is easy to follow it down and take the reading at its bottom which is, of course, the top of the mercury column.

What Usually Causes the Scoring of a Journal?

By THOS. H. FENNER

Editor of "Power House" Meets Former Editor of Canada's Power Plant Newspaper at U. C. C. of E. Banquet, as a Result Readers Get This Article on Hot Bearings

IN A RECENT issue of "Power House" the statement was made that a scored crank pin could be cured by lapping it, with a canvas cloth on which emery paste had been laid. It was also stated that if the pin continued to work hot after this treatment white lead would smooth it down.

Regarding the first part of this statement it would be a tedious operation, in the writer's opinion, to attempt to reduce the grooves caused by scoring in this manner, were the pin of any size.

The probability of white lead having any smoothing effect would also be remote.

Scored pins or journals of any kind should be a rarity in modern practice. In the old days, when bearings were made of brass, they were unfortunately only too common, but with the modern white metal bearing surface, a scored journal would be unknown.

What Causes Scoring?

In the first place, let us ask: "What causes scoring of a journal?" It is obvious it is friction from a surface or point that at the moment the scoring occurs, is harder than the surface of the journal.

Taking the old type of brass bearing first, these were often made of very hard material, and this tended to become surface hardened with continued use. As many shafts and crank pins were made of wrought iron, overheating of bearings was frequently followed by fairly deep scoring, both in the journal and the bearing. This was particularly the case where water had been used on them for prolonged periods, as was frequently the case in marine practice.

In this case there is no doubt that a part of the scoring was due to the corrosive action of the salt water used for cooling, in conjunction with the brass iron of the bearing and journal.

We may presume in the case of the brass bearing that overheating caused distortion of the brass, which resulted in a diminished bearing surface. The local heating in the spots that were bearing on the journal under this condition would then be intense, resulting in the breaking of the skin of the journal, from which would occur the grooves.

In the case of bearings with brass or cast steel shells and having babbitt metal bearing surfaces, scoring occurs through a somewhat different process. The cutting of the surfaces in this case is either caused through the babbitt having been allowed to wear down until the chipping strips of the shell have come in contact with the journal, or the babbitt has melted out of the shell, bringing about the same result.

Causes Deep Grooving

In whichever way the scoring is accomplished, the contact of the cast steel shell of a babbitt bearing with the journal results in immediate and usually deep grooving.

For the moment, so much for the causes of scoring. Before going into the question of the proper treatment, let us examine the statement that white lead acts as a smoothing agent.

White lead, as a temporary remedy for overheating, on certain types of bearing, has a wonderful effect. The place where it is most suitable is on a bearing where both rubbing surfaces are cast iron, such as the shoe and slipper of engine guides.

The writer has used it on this type of bearing on many occasions, and always with satisfactory results. It will, however, have no effect on the condition which caused the bearing to heat up in the first place.

To use a medical metaphor, it acts exactly as a salve applied to an external sore. The salve alleviates the external condition, but leaves the internal cause untouched.

The reason white lead has such a good effect on this kind of hot bearing, is because it requires considerable heat to make it flow, and this heat is taken from the bearing which is to be cooled.

It also has certain lubricating properties which water lacks. It does not fly off the face of the guide, but is carried up and down with the shoe, reaching all parts, and it has no tendency to cause sudden contraction and cracking of the cast iron, such as water has.

Lacks Abrasive Qualities

Another point is that it does not spray all its immediate surroundings, including the man who is applying it, as a stream of water directed against a moving object, such as a guide shoe, will do. It has no abrasive qualities, so cannot have any smoothing effect. It is suitable only for guides, because in any enclosed type of bearing, it is impossible to apply it.

Having thus disposed of white lead, let us look into the primary cause of hot bearings.

The first cause may be stated as, bearing set up too tight. The second as, bearing set up too slack, or worn slack. Third, bearing not receiving sufficient lubrication, and fourth, bearings out of line. In the case of the guide, which we have been discussing, there is another cause, which does not apply to the other types of bearings. The first three cases all practically amount to the same thing, and that is insufficient lubrication.

In order to ensure successful working there should be at all times a film of oil between the surfaces of the bearing and the journal surfaces. This is best achieved by forced lubrication, but can be attained with ordinary methods.

In the case of the bearing being too tight, there is no room for this oil film. If the bearing is too slack the oil runs out, or is splashed out at the ends by the continual hammering of the slack parts. If there is not enough oil given to the bearing the oil film disappears, and there is direct rubbing of the surfaces.

All three conditions result in overheating, and the cause in each one is insufficient oil or want of lubrication.

Bearings Out of Line

The fourth case, bearings out of line, is less frequent than the other three. When this condition is present it results in the load, for which the whole bearing surface has been designed, being carried on only a small portion of it. There is also often a side rubbing action on surfaces never meant to be in contact, as for instance, the cheek of the crank web. Where there is a fillet, considerable side friction is often thrown on this fillet. The result of the diminished bearing surface is to throw a greater pressure per square inch on those portions that are bearing than was ever intended, and the result is a hot bearing

Guide shoes and slides may be overheated due to a running condition, which occurs chiefly on compound engines, but may occur in a single cyinder job. It is not an unusual trouble on marine jobs, and in certain types of stationary work. It is due to a very light load, which in the case of compound engines, results in the low pressure cylinder doing no work. The low pressure crank is then carried around by the high pressure, during portions of the stroke, and if there is any slack in the guides, a slapping action is set up between shoes and guides which often results in very rapid heating up.

The same thing may occur in a single engine, where the flywheel is carrying

Pointers on Proper Commutator Maintenance

With Direct Current Motors 90 Per Cent. of Troubles Due to Neglect—Maintenance Rules Simple but Must be Rigidly Adhered to—Compressed Air Convenient Cleaning Medium

WHEN the word comes to the engineer in charge of a plant that a motor is not acting properly, his thoughts immediately concentrate on one particular part of the machine, namely, the commutator.

A large percentage of motor trouble can be traced directly to that important member. It may properly be termed the business end of the motor, and it is good policy to see that it gets the best of care and attention.

Most text books on electrical machinery give a lengthy list of probable causes of motor troubles. However, the purpose of this article is to give a few hints on the care of commutators from the viewpoint of the man directly charged with the responsibility of continuous operation. All the cases and remedies mentioned herein have been encountered in actual practice, and it is the earnest hope of the writer that some of them may be of benefit to readers of Power House.

Abide By Simple Rules

To ensure that smooth glossy, chocolate color of commutators so much sought by operators, several simple rules must be formulated and strictly adhered to by the engineer. Rule number one is that a regular daily inspection be made of all motors. It is only in this way that one can keep in touch with each motor's peculiarities, and promptly check any irregularity that may arise.

It is necessary to clean motors periodically. Compressed air is best for this purpose. The armature core should be thoroughly cleaned, especially the ventilating air ducts through the core, which are put there for the express purpose of creating a current of air through the core, thereby carrying away much of the heat generated in the armature windings. It is by no means an uncommon occurrence to find these ducts completely clogged with solid matter.

With motors operating in dusty places, particles of dust and the product of manufacture will often collect on the brush holders to a considerable extent. Under such conditions sparking at the brushes is not only dangerous to the motor, but the fire hazard to the building is greatly increased due to the possibility of flying sparks.

Clean Once a Day

Rule two is that all commutators should be wiped clean with a soft cloth each day. This is a very simple operation, but a very important one. Ninety per cent. of motor troubles originate from neglected commutators being allowed to get gummy with oil leakage from the motor bearings. Together with carbon and copper dust the oil will form a gummy smear on the commutator surface, the brushes then become saturated with it, and from that point it is but a short step to costly repairs.

A mixture of carbon and oil is a conductor of electricity, and it will eventually soak into the mica segments, resulting finally in leakage of current from bar to bar. A small arc will be set up between the two bars. This arc may burn itself free, but in the majority of cases it will increase in intensity, resulting in a burn-out between bars. Frequently food armature coils are ruined from the fusing together of two bars.

A clean commutator and brushes, kept dry and free from oil, will very rarely show signs of burning between bars. With this hazard eliminated the operator has taken a great step towards reducing to a minimum costly motor shut-downs and repairs. Therefore, make it a positive rule to keep every commutator on the job perfectly dry and clean.

Sandpaper a Nuisance

Sandpaper has no logical place in the operation of commutators, and the farther away it is kept from the smooth surface of a mass of copper and mica, so much the better for motor harmony. The same may be said of commutator compounds—that black, gummy stuff so often passed on to the man in charge as a cure-all for motor troubles. These compounds are largely a lubricant, and if lubrication is needed use paraffin or a small amount of machine oil, applied with a cloth.

Frequently troubles arise due to other causes. Glowing of the brushes at the surface of the commutator sometimes occurs. This can be due to a number of causes, such as incorrect brush position, brushes not properly spaced, high mica, and brushes covering too many bars. One serious case of glowing was corrected by substituting brushes ⅛ in. narrower than those in use.

Sparking Common

Sparking due to burnt spots on the commutator is a very common occurrence. These spots may be equally spaced, or they may occur at irregular intervals. In either case the cause of this particular trouble is often hard to locate. In one instance it was found to be caused by a loose coil connection to the commutator. The trouble was further aggravated by the fact that this loose connection was what is known as a "flying open."

Violent sparking would occur when the motor was in operation, then suddenly the sparking would cease. This would go on intermittently during the day. The trouble was finally traced to the loose armature lead, which would make and break contact, probably due to variations in the motor speed.

Open Circuit Effects

Effects of a dead open circuit are very apparent. There is a violent, snapping, bluish-green spark at each brush edge as the bar of the open-circuited coil passes beneath each set of brushes. The spark seems to reach out from the brush edge, and attempts to follow around the commutator. The bars to which this coil is connected will be found to be burned and pitted, and the mica segments between eaten out to a considerable depth.

In another case, black spots were found to be caused by one set of brushholders moving out of proper alignment. A strip of heavy paper was drawn about the commutator and the brush positions marked. The paper was than withdrawn and the marks measured. They were found to be unequally divided. The strip was then marked off in four equal divisions and the brushes set to these marks.

An overloaded motor will often produce burnt spots on a commutator. A frequent cause of burning is due to high mica. All or nearly all the bars will be found in this condition, leaving the mica segments protruding slightly above the surface. Continual sparking and heating results, due to poor brush contact. If this condition persists for any length of time, the commutator will become hot enough to melt the solder from the coil connections. A shut-down and a repair is then a certainty.

High Mica

In some cases, high mica is the result of several conditions in no wise chargeable to the operator. One of these is that the mica is of too hard a grade. The copper wears faster than the mica, leaving it protruding above the surface of the copper. Another is that the copper bars are considerably softer than the mica. This condition will produce the same result. Segment copper is usually drop-forged or hard-drawn. With hard-drawn bars the copper and mica will usually wear evenly. It is with cast-copper bars, formerly largely used, that most of the high-mica troubles arise.

Most of the men in charge of electrical equipment will work out their own salvation when troubles arise. Some will be content to turn down the commutator occasionally, and let it go at that. This method will give a smooth-running machine for a short time, but it is costly in labor and greatly shortens the life of the commutator. Some of them will be

Modern Practice in the Transmission of Power

With Drives From Gas Engines to Dynamos Engineers May Find a Little "Slip" Will Allow the Shock of the Explosion to Pass off Without Light Flickers

MANY engineers calculate the efficiency of a belt drive from the arc of contact on the smaller pulley. This arc of contact can be found by the simple rule of multiplying the difference between the diameters of the pulleys in inches by 4.75, dividing this product by the distance between pulley centres in feet, and then subtracting the quotient obtained from 180°.

It is wise not to have less than 168° of arc of contact, although any small reduction in this arc can be offset by the use of a wider belt.

It is obvious, however, that this cannot be done when the arc is less than a certain figure, as the belt will not wrap round the pulley sufficiently for it to get any grip.

Increase Arc of Contact

The use of tension pulleys on drives with high speed ratios and short shaft centres is sometimes advised. The tension pulley apparatus usually takes the form of a single pulley mounted on an arm which is pressed by a spring or weight so that it presses into the belt and takes up the slack, besides increasing the arc of contact on the smaller pulley.

Compared to the loss of power and continual troubles experienced with a drive with too high a speed ratio or too short centres, this tension pulley apparatus gives better efficiency; but experience has shown that this efficiency is much lower than that of a properly planned drive.

As compared with a free drive, a tension pulley brings from 20 to 30 per cent. more of the belt in contact with the driven pulley, yet this gain is secured at much cost. The pulley itself is a very expensive rig up. It acts like a brake upon the belt, and this is done at the cost of a large amount of horse power. The life of a belt so driven is a very short one compared to what it might be were it working as an open drive. The strain put upon the belt at the short distance between the bottom of the pulley and the point of contact with the driven pulley is enormous.

Oil Causes Trouble

By consigning the tension pulley bag and baggage to the scrap heap and running compound belts instead, there will be a gain of 70 per cent. in power, the drag taken off the engine, and a large saving of coal and lubricating oil secured. Waste oil from the tension gets on to the belt causing stretch and preventing the gripping power of the belt from doing its work.

These disadvantages may be attributed to two causes: (a) Double bending of the belting at points very close to each other; (b) tight belting. By far the majority of the troubles are caused by tight belting, which is a continual source of expense and annoyance. It may waste an enormous amount of power, and the gain of 70 per cent. mentioned above would be chiefly due to dispensing with tight belting.

Whenever a drive slips badly or will not take a heavy enough load, compounding the belts may solve the difficulty.

Run Tandem Belts

By running a second belt on the outside of the existing belt, 50 to 70 per cent. more power may be taken on a drive. The second belt tends to run a little faster than the belt next to the pulley face, owing to the diameter of the pulley being increased by the thickness of the belt underneath. This creeping of the outside belt tends to reduce slip and the effects of centrifugal force.

There are some cases where a little belt slip is useful; for example, with drives from gas engines to dynamos, a little slip allows the shock of the engine explosions to pass off without causing a flicker of the light or an unsteady supply voltage.

It is not wise to bend thick belting round very small pulleys, as some power is then wasted in getting the belts round the pulleys, and the belt is liable to be damaged. When driving on pulleys of 4 inches diameter and under, the belt ought to be barely ⅛ inch thick, on pulleys 4¼ inches to 8 inches diameter, not exceeding 5-32 inch thick, on pulleys 8¼ inches to 12 inches diameter not exceeding 3-16 inch thick, and on pulleys 12¼ inches to 18 inches diameter not more than ¼ inch thick. On pulleys over 18 inches diameter, double leather belting can be used with ease.

If the pulleys of a drive are too small for a very thick belt to be used, and there is not room for a very wide belt, compounding the belt will enable the desired amount of power to be taken. If necessary a third belt can be run on the other two belts, although this will not increase the capacity of the drive proportionately.

A safe working tension for single leather belting is 50 lbs. per inch of width, and for double leather belting 80 lbs. per inch of width.

Increase Belt Speeds

Horse-power being a product of feet per minute and effective pull in lbs., it is easy to increase the load of a drive by increasing the belt speed. This is a very simple solution to many belt transmission troubles, which is often overlooked.

For instance, if a 9-inch pulley is driving on to a 27-inch pulley through a 6-inch single leather belt, and it is desired to increase the load 33 per cent., by substituting 12-inch and 36-inch pulleys the same belting will take the load, and providing the shafting is capable of carrying the increased load, this is all that need be done to the drive.

Centrifugal force necessitates a limit to belt speed, the safe economic limit being 1 mile per minute or a belt speed of 5,280 feet per minute. Compounding the belts will enable higher belt speeds to be used, but it is wise not to exceed this figure, as this speed also coincides with the safe limit of periphery speed for cast-iron pulleys of ordinary construction.

Prevent Slip With Tallow

Some care of the belting is necessary to ensure satisfactory service. Dust should not be allowed to form into cakes on the pulley face or belting, as these prevent pulley and belt getting proper contact, and cause slipping. The life of leather belts can be lengthened by an occasional washing and brushing in warm water, afterwards greasing with melted tallow. Pure beef tallow is a very fine slip preventive and keeps the belts in good order. After this treatment the belts should be carefully and thoroughly dried before being put into use again. The use of resin defeats its own object and makes the leather hard and brittle, besides forming cakes on the pulley face and causing slip.

Chain Positive

The chain drive has come into favor for the transmission of power, owing to its positive drive and high efficiency. Opposition is sometimes given to chain drives because of their positive drive, it being thought safer to have a flexible link in the power chain so that at any undue strain this is the part to give. Belting fulfils this conditions admirably, but there are many cases in which it is very inefficient and the chain drive is the only satisfactory method to employ.

An efficiency of 98 per cent. for ordinary commercial drives, and 99 per cent. for efficient drives is claimed for chain driving. These efficiencies are much higher than that of the average belt drive, and indicate the great possibilities of chain driving.

Hints on the Cleaning and Handling of Motors

By J. J. CURTAIN, General Electric Co.

Proper Lubrication, Inspection and Adjustments Will be Amply Repaid With Dependable Service if the Initial Installation Has Been Properly Made

CANADIAN engineers should be impressed with the fact that a small amount of time given regularly to the cleaning, lubricating, inspection and minor adjustment of electric motors, will be amply repaid with dependable service from the motor and prolonged life of the electrically driven machine, assuming, of course, that the initial installation has been properly made and the motors rightly chosen to fit the service.

Proper motor installation involves some important considerations. The shaft should always be level, and correct alignment and proper distance should be maintained between motor pulley or pinion and the corresponding pulley or gear of the driven machine.

In case of belt drive, an endless belt should be used in preference to a laced belt. Care should be taken that the belt is not so tight as to cause undue wear or heating of the bearings or so loose that slipping will take place.

Allow Gentle Sag

In the location of shafts that are to be connected with each other by belts, care should be taken to allow of a gentle sag of the belt when in motion. It is desirable that the angle of the belt with the floor should not exceed forty-five degrees.

In the event that a number of machines are group driven it is preferable to locate machinery so that belts may run off from the shafting in opposite directions, as this arrangement will relieve the bearings from the extra friction and wear resulting when belts all pull one way.

Those pulling in opposite directions should be placed as near each other as practicable, while those pulling the same direction should be separated. By this procedure much of the friction on the journals may be avoided.

Cleanliness Important

If a dusty, dirty, or damp place is unavoidable, protection in the form of enclosing covers for the standard open motor or enclosure of motor by boxing should be employed. It should be remembered that in proportion as enclosure affects the natural property of an open motor to radiate its heat, provision must be made to balance this changed condition either by reducing the load on the motor or by some special provision whereby cool air may be introduced from an external source.

Enclosure of motors (by boxing particularly) should not be effected without exercise of proper precaution against possible overheating of motor. It is best to consult the motor manufacturer or competent repair man in such cases.

With motors without commutators the necessity of enclosing covers to protect the motor from dust, etc., is not so important, though it is always advisable to make the installation in as clean surroundings as possible. Dust, dirt and moisture can readily be wiped off the motor exterior, while dust may easily be blown from the interior parts with the aid of a small hand bellows or other source of compressed air.

Bearings and Lubrication

It is essential that bearings receive proper lubrication. The usual motor bearings have oil fed to them from reservoirs by rings which are hung on and turn slowly with the shaft, continually bathing the shaft and journal in oil. While the motor is at rest, the reservoirs would be filled (through the oil filler gauges usually provided) with good clean mineral oil till the oil level is just below the top of the oil gauge. As long as this level is maintained no more oil need be added.

Oil should not be poured through the hole at the top of the oil well, as the correct oil level in this manner is apt to be exceeded; furthermore, excess of oil is likely to result in overflow of the oil well into the armature or field coils, eventually weakening their insulation.

An occasional flushing out of the complete bearings and gauge with kerosene or gasolene is recommended, after which a new supply of clean oil should be used. At that time it is good practice to remove the oil well covers and see that the rings turn freely with motor running.

Direct Current Machines

With proper care a new commutator will soon take on a dark brown polish and then the only attention required is an occasional wiping, while running, with a piece of canvas (4 oz. duck). A new or newly turned commutator should be cleaned daily at first, till the brushes reach a good fit; this to prevent roughing, which occurs more readily than after the commutator has become polished. Excessive sparking tends to burn and roughen the commutator.

If sparking continues after the commutator has been cleaned as described above. the surface should be smoothed. either by using a piece of sandstone from which a segmental piece having the same radius as the commutator has been cut, or by pressing a piece of very fine sandpaper (never emery cloth) against the commutator with a block of wood shaped like the sandstone just mentioned.

The sandstone or paper should be moved back and forth parallel to the shaft while the motor is running at full speed. The commutator and brushes should be thoroughly cleaned after this operation.

Brushes and Adjustments

Brushes should be inspected frequently to see that they move freely in the holders and make firm and even contact with the commutator under the proper spring tension. As brushes will wear out in time it is well to keep a spare set on hand. When a new brush is put in, it should be fitted as follows:

A strip of fine sandpaper, a little wider than the brush, should be placed under the new brush after it is in place in the holder. The paper with the rough side against the brush should be drawn in the direction of rotation of the armature with the maximum tension of the spring exerted on the brush. Lift the brush to push the paper in the other direction. Repeat this operation until the brush has been shaped so as to make a firm and even contact with the commutator.

After cleaning away the carbon dust the motor is ready to operate and the commutator surface will soon take on a polish. Care should be exercised to see that the "pigtails" or flexible copper conductors are firmly fastened in place, so that they will carry the current from the brushes to the brush-holder proper. Caution should be observed to leave a light play in the pigtails, since if too tight they might tend to pull the brush out of line and also out of proper contact with the surface of the commutator.

The part of an induction motor that needs the closest inspection is the air gap clearance. This clearance is necessarily small. While the air gap is equal on all sides of the rotor, the magnetic pull will be even, but when, through bearing wear, the rotor drops down the forces become unbalanced and the tendency of the motor to rub against the stator on the wearing side is increased.

The air gap should be regularly tested with a gauge and this test should be verified by a visual inspection when the motor is running.

Electricity in the Power House

By J. A. BURNETT, M.E.I.C., Consulting Engineer, 205 St. James St., Montreal

PRACTICAL EXPERIENCE

ON ONE occasion a trouble man had been sent out to investigate troubles with a direct current motor starting rheostat, and had discovered a large momentary current in starting. In this case a 30 H.P.-110 volt motor drew 400 amperes from the line. This was the result of a weak field due to wrong connections as shown on Fig. 1. The correct method is shown in Fig. 2.

Starting Box Reversed

The writer had occasion to instal an overhead traveling crane with one motor for lift, as well as one for travel and cross travel of car. The lift motor started very badly, and it was found that the starting box (rheostat) was so connected that the high resistance units came last and the low resistance units first, i. e. "backwards." Naturally this was re-connected with excellent "pick-up" for the motor.

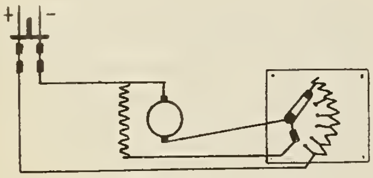

Fig. 1.

Bad Commutation

A large generator would not commutate well on heavy loads. It was found that the machine was guaranteed to over-compound from 550 to 600 volts, at 100 r. p. m., but on account of having to work in with other machines on a large system, it could not be operated above 550 volts as a maximum.

This caused the machine to work low on the saturation curve, and slight sparking at some points with a constantly shifting load. As the engine was relatively large compared with the generator, it was decided to lower the speed to 90 r. p. m. and work the field more nearly as designed. This change made the generator satisfactory to the local company.

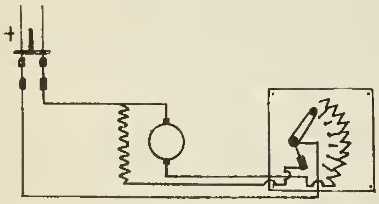

Fig. 2.

A rotating field alternator hummed badly, and investigation showed that the finger plates on the stationary armature were not stiff enough to hold the outer laminations firm between the coil slots. Several efforts were made to stop the trouble by upsetting the iron finger plates, without entirely stopping the trouble. Finally thin strips of mica were driven between the iron laminae, after having been coated with shellac. The method was successful.

Two belted alternators had never been successfully operated in parallel, although driven from the same shaft, and with pulleys of apparently the same diameters. A steel tape was run over each of the driving pulleys, and a difference in circumference of more than an inch, was found, as the driving pulley could not readily be turned, one of the driven pulleys was taken off and turned down to give the desired speed.

A lot of transformers connected in delta and in a system with a large amount of other apparatus, was found to be running too hot. Tests were made of efficiency, iron loss, regulation, cross currents, power factor, etc. Then someone discovered that the oil was low. When the oil was brought up to its proper level, the temperature went down to where it belonged.

A complaint was made that a compound-wound direct-current generator, in service more than a year, did not compound properly, and the switchboard attendant had frequently to adjust the voltage. Investigation showed that the load had been put between the negative and the equalizer, cutting out the series coil. When the matter was explained, the local electrician said he felt like an old man, who, after forty years, discovered that the clock he had wound daily was of the eight day variety.

Westinghouse Company In Japan

Gen. Guy E. Tripp Announces Formation of $7,500,000 Concern to Manufacture Electrical Machinery and Supplies

THE report of an arrangement between Westinghouse and Japanese electrical interests for the formation of a Japanese electrical manufacturing company, is confirmed in a cable this week from Gen. Guy E. Tripp, chairman of the Westinghouse board, and L. A. Osborne, president of the Westinghouse International Company, who are now in the Orient.

Fear Trade Balance

"The new company is known as the Mitsubishi Denki Kabushiki Kaisha, or in English, the Mitsubishi Electric Manufacturing Company," states E. D. Kilburn, general manager of the Westinghouse Electrical International Company.

"As a consequence of this rapid development, electrical apparatus has become one of Japan's largest imports, and since Japan's principal exports, silk, copper and objects of art, cannot be expanded by a corresponding degree, the Japanese began to feel that there was danger of a continuing unfavorable balance of trade. Hence it seemed wise to Japanese interests to begin the manufacture of electrical machinery and supplies in their own country.

"In pursuance of this policy, the important Mitsubishi interests which are engaged in banking, shipbuilding and steel making, approached the Westinghouse Electrical Company with a proposal for a co-operative agreement whereby the Westinghouse Company was to supply technical skill and experience to a Japanese manufacturing company.

"The Mitsubishi Electric Manufacturing Company is the outcome of these negotiations. The Japanese profit by the arrangement because of the employment it will give to Japanese workmen and the improvement in their foreign trade situation, while the Westinghouse Company profits by receiving a continuous revenue for service and royalties in lieu of exports, that it was certain to lose within a comparatively few years.

"The Westinghouse Company has subscribed for a portion of the stock of the Japanese Company.

"A third party to the agreement is Takata and Company, Japanese importers, 30 Church Street, New York. This concern which is the Japanese agent of the Westinghouse Company, will play a large part as distributor for the Mitsubishi Electric Manufacturing Company, and will also continue to import such Westinghouse products, as will be supplied from the American continent."

Practical Ideas From Practical Men

SHAFTING PROBLEMS

THE writer has taken a keen interest in power transmission matters during the past 15 years and has at this time a few remarks to offer which he hopes may be of interest and value.

An excellent way in which to align shafting longitudinally is to simply permit plumb bobs to be suspended around the side of the shaft, as indicated in the sketch. If several such plumb bobs are suspended in line, at least three of them, the engineer can see with his eyes whether or not the shaft is in alignment, and if the plumb bobs are very far apart he can stretch a thread close to the vertical threads leading to the plumb bob and measure the mis-alignment with accuracy.

The plumb bobs suspended in this way are all perfect tangents to the shaft and, knowing the diameter of the shaft, there can be no question as to where the centre of the shaft is all along the line.

On the other hand, in the case of aligning certain apparatus the writer has seen, the accuracy of the apparatus itself may be questionable, whereas with the plain suspended plumb bobs there can be no question at all.

Vertical Alignment

For aligning shafting vertically, the writer does not know of a better method than the use of an ordinary garden hose filled with water, with gauge glasses inserted in the ends, as indicated. No matter how far the ends of the hose are apart, the water will always assume a perfect level and the engineer can be certain whether or not the shafting is absolutely level.

The writer has seen this method used not only for aligning shafting but for laying foundations for machines and buildings and even for laying large floors.

Not long ago, in a prominent American newspaper, the following method was proposed for balancing pulleys. The author said:

"To counteract this extra weight, plant a bit of putty on the inside of the rim opposite the heavy side. By making a few trials with different amounts of putty, at different points on the inside of the rim, the pulley can be brought to a good standing balance. Never try more than one pulley on the shaft at a time. When a balance is temporarily made in this way, remove the putty, weigh it and substitute permanent weight slugs in the form of one or more pieces of strap iron. The weights should be securely bolted in the middle of the inside of the rim, not to one side of the web, because this would impair or destroy the line balance."

This method of balancing is inadvisable, because of the difference in weight of putty and iron per cubic inch.

If putty weighed exactly as much as iron weighs, and if the putty could be molded onto the pulley exactly as stuck in place in the same form and in exactly the same position, without any additional weights due to bolts, nuts, rivets, or anything else, a perfect standing balance could be brought about.

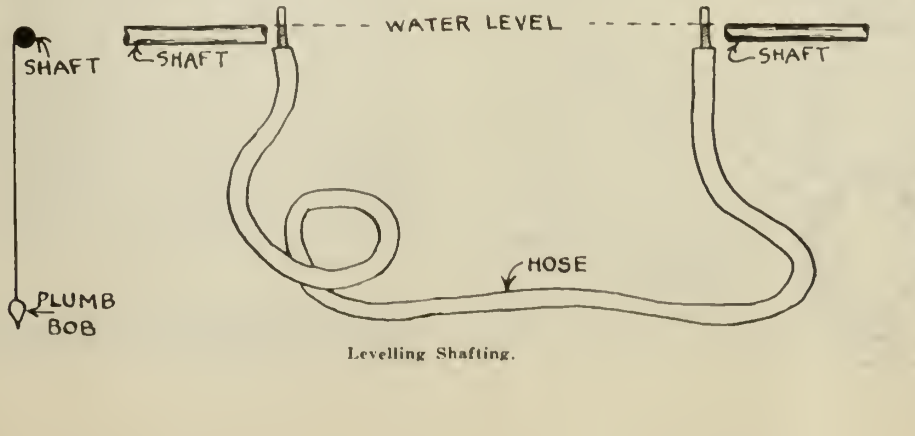
However, it is manifestly impossible to do an accurate job in this way because the iron slugs that will be bolted in place are heavier per cubic inch and consequently the mass is liable to be farther away from the centre of the shaft, and just as soon as the weight is farther away from the centre of the shaft the pulley is bound to be thrown out of balance again.

Also, in order to fasten the weight onto the pulley, bolts, screws, or metallic cement is required, and since all of these things have weight and are heavier than putty, their respective weights must be given consideration.

A better way to balance a pulley, if it can be done at all, is as follows:

"If a pulley is out of balance only slightly, it may be balanced by removing weight from the heavy side instead of adding weight to the light side—usually by boring one or more holes in the rim on the heavy side. Care must be taken, however, that the removal of this weight does not weaken the pulley."

The best way of all is a combination of the two above methods. Use the putty method "approximately" so that the slugs bolted to the pulley will be slightly lighter (not heavier) than the other side of the pulley. Then, to make the pulley balance, drill away a little metal from the opposite or heavier side and by cutting and trying a true balance is quickly attained. In this way the strength of the pulley will not be impaired by excessive cutting, and the desired balance will be found more quickly.



Levelling Shafting.

Another mistake commonly made is to neglect the thickness of the belt when making pulley speed computations. Belt thickness is often an important factor, especially on small pulleys.

Thus, to find the correct speed of a belt in feet per minute, add the thickness of the belt in inches to the diameter of the pulley in inches and divide by twelve. The result is the diameter plus the thickness in feet. Then multiply this by 3.1416 and then by the r.p.m. of the pulley and the result is the speed of the belt in feet per minute, assuming there is no loss due to creep.

In figuring the revolutions that will be made by a driven pulley, this matter of creep and belt thickness must always be remembered.

The correction to be made for creep depends upon the belt. For balata belting, friction surface rubber belting, and stitched and filled canvas belting, the writer usually allows one-half of one per cent., and for solid woven cotton belting, one per cent. For leather belting it is proper to allow one half of one per cent. to three per cent., depending upon the load transmitted. Creep depends entirely upon the elasticity and loading of the belt. Leather is more elastic than substitute belting, consequently a more variable allowance must be made. —W. F. SCHAPHORST.

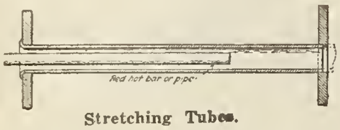
STRETCHING TUBES

Stretching boiler tubes on repair work or new work under construction injures the tubes and may endanger the lives of any persons who may be in the vicinity of the boilers in the event of the tubes rupturing. The stretching of the tubes is performed in the following manner:

A sufficient length is allowed at one end. The tube is then expanded in place, the expander removed and the tube flared and heated. A long pipe or bar is heated in a furnace and then placed into the tube. The tube expands to the point of the least resistance, and when sufficient length is secured, the heated bar is withdrawn from the tube and the opposite end is flared and expanded before the metal has any possible chance of shrinking to its original position.

Naturally, under these conditions, the tube sags and a strain is brought upon the tube close to the head. Moreover, the sagging makes it difficult to clean out the tube properly.

These conditions can be avoided only in the boiler shop by laying out the boiler plate so as to allow sufficient length for a standard size tube. Furthermore, it is important that a strong back be applied to each head and the tube sheet properly leveled before any tubes are expanded. If the tube-sheet flange should be slightly out of proportion, the next longest tube should be cut to suit the required length.



Stretching Tubes.

If a boiler already in service has developed a bulge in the tube sheet or headers and if the standard size tube which the boiler was designed for does not come within the required length, a new tube of extra length should be ordered immediately.

—ONTARIO INSPECTOR.

STEAM RISER SLEEVE

As a rule fire or building regulations require that steam risers be covered with some kind of sleeve where they pass through floors. Engineers are well aware that the proper fitting of such sleeves is often something of a difficulty. When a pipe line runs straight through a ceiling, all is well and good. The sleeve is fitted into place and quickly cut off at the desired length. The top rim will then be cut in a number of places with a pair of snips and the separate segments bent over so as to form a flange on the floor. This holds the sleeve in place, both on the floor above and at the ceiling below.

The difficulty comes when there is one or more T branches or other fittings between the beams. In such cases the sleeve must be cut away so much that it is difficult to make a workmanlike job of it and have it stay securely in place.

The engineer of a large office building in Montreal has noticed this condition and endeavored to solve the problem. By arrangement with a sheet metal worker, he has had special sleeves made for his own purposes.

Fig. 1 shows a drawing of the type of sleeve used. The part expected to fit securely on the ceiling below is the one that usually gave trouble. This engineer has arranged for short sleeves, which will fit properly over the pipe line at the ceiling, and be held in place by two or three long straps riveted to the short sleeve at one end and nailed to adjoining beams at the other. This short sleeve has the escutcheon built into it just as the ordinary sleeve has, but it is only about three inches long and tapers immediately at the upper end so as to fit accurately the particular size of pipe. These sleeves are made in the different pipe sizes, just as the other sleeves are.

When this engineer has any repair work to do where there are branches in the risers between the beams, he uses the special sleeve at the ceiling. When the pipe line is in place it is then easy enough to make a sleeve for the upper part out of a plain piece of tin or galvanized iron. The upper part of the sleeve can be cut out, so as to fit around the branch, and the sleeve can be dropped into place easily and quickly and tacked down, if need be. The all-important part of having the ceiling end of the sleeve level in its place and held securely is accomplished only through use of the specially designed arrangement.

OIL PUMP TROUBLE

I was given the job of locating trouble on a duplex oil pump. The pump would lose its suction and race. It had been to a machine shop and overhauled, but still gave trouble. Upon investigation I found that the suction valves were not seating properly.

I used a scraper on the brass disks until they all seated as they should. Upon trying out the pump, the racing had been removed, but the pump would stop occasionally. This was due to its becoming gas bound. There was a 1-32 in. hole in each of the discharge valves originally, but the shop, in overhauling the pump had soldered these up. After these were drilled out, there was no more trouble. —MONTREAL ENGINEER.

Every-day Problems With Answers

Queries are invited on the every-day problems of all industries. Read the questions and answers. If you have had similar problems, or know from experience how the condition can be remedied, do not hesitate to send in your comment or criticism. It will be some satisfaction to you to know that you have helped to solve a problem and a pleasure for us to pass on the data.

HEIGHT OF BRIDGE WALL

What is the proper distance between the bridge wall and the bottom of the shell of a 50 h.p. return tubular boiler? The bridge wall in our plant has been knocked out and in my opinion it is now much too low, the fire catching the shell almost at the back of the boiler.

Coal is burned in the winter months during the day and shavings and cuttings from the saws during the night. In the summer nothing but shavings and cuttings are burned.

The Dutch oven furnace is 12 feet by 4 feet 6 in. Natural draft only is used.

—ARTHUR SHEPLEY, Hamilton.

Ans.:—There is really no "hard and fast" rule as to the distance between the bridge wall and the bottom of the shell, however, there are a few rules which may be of some help to you in checking up the present height of the bridge wall in your plant.

The purpose of the bridge wall is chiefly to prevent the fuel from falling off the back end of the grates. Some claim that the bridge wall holds the heat to the boiler shell. Hot gases rise because they are lighter than cold gases, therefore, the hot gases will tend to stay against the boiler shell.

Some engineers however claim that they have secured better results by "holding" the fire next the shell by having the bridge wall and the combustion chamber built close to the shell.

For a 50 h.p. boiler the most common height of bridge wall is about 15 inches.

The area between the bridge wall and the shell should never be less than one-eighth the area of the grates.

CHARGING BATTERY

Can I keep the battery in my Ford car charged through the winter months by attaching it to a socket in the house? If it is possible to do so, explain the proper method in Power House.—GEO. THOMPSON, North Bay, Ont.

Answer:—If direct current is available it is possible to charge a storage battery by connecting the battery to the supply through a suitable resistance, commonly a bank of lamps. This method however is wasteful, although it involves very little expense.

In North Bay, the supply from the Hydro-Electric is 60 cycle alternating current. Storage batteries can not be charged by alternating current. To change the alternating current to direct current, the following three methods are in common use:—

Rotary converters.—These are confined to large powers as in central station work so need not be considered here.

Motor-generator sets.—In the motor-generator set a generator giving direct current of the proper voltage is connected to a motor which is supplied with the alternating current.

Rectifiers.—There are three common types of rectifiers on the market, the mercury arc, the vibrating armature, and the selective spark-gap.

They are in fairly wide use where only an alternating current supply is available, and where it is desirable to use relatively small quantities as in charging storage batteries.

It is not possible, under your present conditions, to charge a battery in a car by connecting to a socket in the house. If the supply is direct current, a resistance would have to be placed in the circuit; if alternating current only is available, it will have to be changed to direct current of the proper voltage by some one of the methods already mentioned.

METERING FEED WATER

I have placed a counter on a direct steam pump used for boiler feeding in order to register the number of strokes the pump makes in one day. From the calculated capacity of the pump per stroke, how accurately can the boiler evaporation be determined and what errors and corrections are introduced?—A. R. NORRIS.

Answer:—For making an evaporation test with reasonable accuracy, the means employed for determining the amount of feed water supplied to the boiler should be checked by calibration of the measuring apparatus before and after the test and under conditions that are identical with those under which the evaporative trial is conducted.

The objection to employment of a pump as a water meter arises from uncertainty in identification of the actual working conditions and, therefore, uncertainty in application of correct calibrations. The amount of slip from leakage of a pump per unit of time, determined with any usual working speed of pump, may be regarded as constant for all speeds and, in new pumps handling cold water, reasonably free from air, the loss of piston displacement from leakage and other causes of slippage is not usually greater than 3 per cent. at normal speed.

However, a computation of pump delivery, although based on piston displacement, actual number of strokes and calibrations, may be in error more than 10 per cent. on account of the difficulty in making proper allowance for variation in the lengths of the stroke and therefore, the metering of the feed water with a direct steam pump, without means of accounting for the variations in length of stroke as well as the number of strokes, could not be considered other than a rough approximation.

REFRIGERATION TEMPERATURES

We operate two machines, one fifteen-ton and one fifty-ton, and run with about 190 pounds high pressure and twenty-three pounds back pressure. Both machines are double acting. Is it best to run the discharge pipes hot or cold?

If we instal thermometers on both discharge and suction sides, what would you recommend the temperatures to be?

—A READER.

Ans.:—It is conceded that vapors from the refrigerator should come back to the compressor as nearly saturated as possible. Thus, in a refrigerating system where the temperature is below 32 deg., frost may form on pipes that are not insulated. When liquid ammonia, or other liquid refrigerant, is carried back mechanically in the suction vapors to the compressor, the frost forms on the pipe connections in a heavy manner; this is termed "Frosting Back."

It is generally accepted that there should be no liquid carried into the compressor; and the gas should only contain a few degrees of superheat in order to make sure that the liquid refrigerant is not being returned to the compressor.

Under the saturated condition of suction vapors, the largest weight of refrigerant will be handled and the largest amount of refrigeration produced.

Since your compressor is a horizontal double acting machine, general practice would seem to indicate that the machine should be allowed to frost back to the suction manifold. This may be regulated by proper adjustment of the expansion valve.

In some plants where the suction pressure is quite low, it is sometimes advisable to allow a small amount of liquid to be carried into the compressor in order to prevent the temperatures from becoming too high at the end of compression. This is necessary to prevent a cylinder with its stuffing boxes from becoming over-heated.

As a general rule, it is advisable to carry the frost line back to a point near to the compressor and to maintain the suction vapors at only five to ten degrees of heat.

It is advisable to instal thermometers on the suction and discharge connections to the ammonia compressor, in order that the degree of superheat of the ammonia vapor from the refrigerating coils may be controlled accurately.

In the case that the suction pressure is 23 lbs. gauge, the saturated temperature corresponding to this pressure would be 10 deg. F., so that under ordinary considerations the suction gases should have a temperature of fifteen to twenty degrees in order to insure that no liquid is being carried into the compressor. Under such operation, the temperature of the discharge gases would be from 220 to 230 degrees.

The installation of a thermometer on the discharge line is not necessary, since the operation of the machine may be controlled by the thermometer in the suction main. The advantage of having a thermometer on the discharge main lies in the fact that in the event the thermometer in the suction main is broken, the compressor may be operated by means of the thermometer in the discharge main, since by referring to the engine room log it would be possible to determine what the suction temperature should be according to previous conditions.

STEAM VALVE LAP

Why is lap given the steam valves of a single-eccentric Corliss engine?

Answer:—It is desirable to obtain early release of the steam after expansion and early enough closure of the exhaust valves to obtain cushioning of the piston by compression of the exhaust. This requires the eccentric which operates the exhaust valves to be set more than 90 degrees ahead of the crank.

With a single eccentric for operating both steam and exhaust valves, without lap on the steam valves, they would open more than necessary for the proper lead before the crank arrived at dead centre for the beginning of a stroke of the piston. Hence the lap is added to the steam valves to delay their opening until the proper time for admission of steam.

—S. HUGHSON

GRATE SURFACE

A cast iron boiler, used for heating an apartment house, is estimated to be twice as large as necessary. Would it be advantageous to build a bridge wall across the firebox so as to reduce the grate surface to half the present area and cover the rear end of the grate with firebrick to form a combustion chamber?

Answer:—Cast-iron heating boilers generally are provided with grate surfaces of sufficient size to require stoking not oftener than two to four hours, when the boilers are operated at proper capacities. Consequently, boilers of this type usually are designed with a fewer number of square feet of heating surface per square foot of grate than customary for power boilers.

Shortening the grate as proposed would require more frequent firing and the extra attention thus required for operating the boiler should be compensated by somewhat greater economy of fuel, although not from development of the proposed combustion chamber, since the furnace gases would have much lower velocity than in power boilers, where a combustion chamber is beneficial in securing better combustion by obtaining more thorough mixture of the furnace gases while at a high temperature.

—C. A. S. E.

AMMONIA CONDENSERS

I have replaced an atmospheric ammonia condenser by a double type condenser. Can the amount of cooling water be reduced? I understand the amount of heat transferred per square foot is higher in the double pipe.

Answer:—To cut down the condensation surface, the final temperature of the water must be raised or the volume of water increased.

For example, assume that a condenser having 60 lin. ft. of 2-in. pipe per ton of refrigeration requires 2 gal. of water per minute per ton of refrigeration, with a final rise in temperature of 10 deg. F. Suppose, now, that this condenser was replaced with one of the later types having only 30 lin. ft. of 2 in. pipe per ton of refrigeration to do the same work. The same two gallons per minute per ton would be required on the condenser having 30 ft. as on the one having 60 ft. if the final temperature of 10 deg. F. is assumed in each case.

—R. KYLE

STEPPING DOWN

Can a ¼-hp., 110-volt d.c. motor be operated on a 220-volt circuit? Is there any means of stepping down the 220 volts to 110?

Answer:—If the load were constant on the motor, it would be possible to connect a resistance in series with the machine to reduce the voltage at the motor terminals. On a shunt machine it will be necessary to connect a resistance in series with the armature and another in series with the field coils. The resistance in series with the armature will depend upon the load on the motor.

At full load the current will be about 2 amperes, and under this condition the necessary resistance to connect in series with the armature will equal 110 ÷ 2 = 55 ohms. The resistance to be connected in series with the field coils will depend somewhat on the design of the motor, but a 25-watt 110-volt lamp should be sufficient. It should be understood that this arrangement is only a makeshift and, unless the load is constant, the speed will vary inversely as the load. At no load the speed will be practically double that at full load.

If the motor is designed for a slow speed, it may be possible to connect a resistance in series with the field winding only and operate the armature directly on 220 volts and at double the speed for 110 volts.

There is no way of stepping the 220 volts down to 110 except with a motor-generator set, which is impracticable. The cost is so slight that the most satisfactory solution will be to rewind the machine, using wire of one-half the cross-section now used and double the number of turns in the coils.

—BOB RIDDLE

HEATER CONNECTIONS

In a plant, operated condensing, the boiler-feed pumps take their supply from a steel tank which receives the returns from the heating system and drips from traps and also the city water supply controlled by a float valve.

The feed pumps discharge through a closed heater set in the engine exhaust pipe between the low-pressure cylinder and the condenser. From this heater the water is discharged at about 85 deg. F. to another closed heater through which the feed pumps and condenser pumps exhaust and in which the feed water is heated above 200 deg. F.

Would it be advisable to pass the city water through the closed heater on the engine exhaust and then through the float valve in the tank, for pumping direct to the second heater, or would that make the water too hot to be handled by the feed pumps, especially when the engine is operated non-condensing?

Answer:—There should be no difficulty in handling the hot water by the feed pumps, but the proposed change does not seem warranted unless operat-

Can YOU Qualify for that Good Job?

HAVE you got a First-Class Certificate? You cannot get very far, cannot make the most money, until you have passed every examination. TORONTO

ing non-condensing is practised considerably, and with low temperature of feed water discharged from the second heater. By admitting the city water to the heater connected with the engine exhaust, this heater would be of only little more assistance to operation of the condenser in receiving city water before it has become warmed by returns from the traps and the heating system, and the small gain for condensing purposes probably would be offset by losses from radiation and evaporation from the receiving tank.

—A. READER

CRANK END NOISE

When starting up a mill engine in the morning, there is in the crank end a grunting noise that lasts for a few minutes, but by the time the engine is up to speed with a steady load, the noise stops. What is the explanation?

Answer:—The irregular resistance when starting up the engine under the load of shafting and, probably also of laying on of machinery, combined with the turning effort of the engine, give rise to vibrations of the engine shaft that are transmitted to the main bearing and to the other parts of the engine.

When the engine gets up to speed, the vibrations are smoothed out and the noise ceases because irregularities of the load resistance and the varying turning effort of the engine are overcome by inertia of the flywheel of the engine.

—M. D. E. A.

HEAT FROM ENGINE

We would like to know the number of sq. ft. of direct cast iron steam radiation per engine horse power which could be heated with exhaust steam with a maximum of three pounds at the engine. The radiation is to be installed in the same building as the engine. We understand conditions will govern, so we wish only an average estimate of radiation which can be heated. Also kindly advise us if a tubular boiler built for power purposes at 125 lb. working pressure, or more, can be used as economically with the use of a pressure regulating valve as a tubular boiler built for low pressure steam at 15 lb. steam pressure. —W. HOLMES

Answer:—There are so many angles to your question regarding the amount of cast iron radiation that can be supplied per indicated h.p. of engine that I can hardly go into sufficient detail to give you a really satisfactory answer.

Originally the terms "boiler horse power" and "engine horse power" were synonymous; they both meant the same —lifting 33,000 lb. per minute—as determined by Watt. It was estimated that 30 lb. of steam was required to develop a boiler and engine h.p.

Now, as improvements have been made to engines, the pounds of steam required for an engine h.p. have been reduced to 25, 20, 15 and, in some highly perfected engines, to 12. Hence an engine h.p. is quite different from a boiler h.p. If the engine develops a h.p. on 20 lb. of steam, 85 per cent. of its heat value is available for use in the heating apparatus. 85 per cent of 20 is 17, the pounds of steam, or equivalent, available.

The total heat in a pound of steam at from three to five pounds pressure is about 1150 B.t.u. 1150×17=19,550 B.t.u. available per engine h.p. If a sq. ft. of radiation gives off 240 B.t.u. 19,550 ÷ 240 = 81 plus, the sq. ft. served per engine h.p. As a radiator at atmospheric pressure gives off about 200 B.t.u., 19,550 ÷ 200 = practically 100 sq. ft. per h.p. of the engine.

Conditions of installation and method of firing will govern the rate of fuel consumption under the boiler, and we doubt if there is much difference between a high pressure or a low pressure tubular boiler as regards fuel consumption, when the former carries 125 lb. pressure (reduced for use in the heating apparatus) and the latter is operated at 15 lb. pressure. Boilers of the tubular type are considered most economical when used with a high rate of fuel consumption per sq. ft. of grate.

Wins Laurels in Power Field

H. W. Weller Now Vice-President in Charge of Eastern Sales of the Babcock-Wilcox and Goldie-McCulloch Company

H. W. WELLER, vice-president in charge of Eastern sales for the recently consolidated interests of Babcock & Wilcox and Goldie & McCulloch, came to Montreal in May, 1899, to be manager for Canada for Babcock & Wilcox. The fact that, during this period of twenty-four years, the water tube type of boiler has won favor in Canadian power plants is in no small part due to Mr. Weller's ability as an engineer and salesman.

The "Babcock" boiler is installed in power plants from the Atlantic to the Pacific coast. The British Empire Steel Co's. interests in Nova Scotia have 150 boilers, the Canadian Pacific Railway has more than 100 at different points along its lines. The Montreal Tramways have 20 boilers, four of which are 1,000 h.p., and are at present installing two rated at 1,200 h.p. each. In the Toronto district, the boilers sold aggregate upwards of 50,000 h.p. The boilers installed in Canada since Mr. Weller has been representative of the company, exceed half a million h.p., and in many cases these boilers are equipped with superheaters and stokers made by the Babcock and Wilcox company.

Mr. Weller was born in 1858 at London, England. He was educated at Derby, later taking honors at Cambridge in 1872, having specialized in chemistry, machine design and construction. From 1873 to 1889 he was employed for the most part by railway and mining interests in the Midlands. In 1882 he made a trip to the United States on special engineering work for Col. Stuart Wortley and, having observed the greater opportunities on this side of the Atlantic, decided to return to New York.

He was in turn with the Sprague Electric Company, the Edison Electric Company and the General Electric Company as a special engineer and assistant manager of the railway department. From 1895 to 1899 he was the New England manager for the Campbell & Zell Boiler Company, and from 1899 to November of this year in charge of the business of Babcock & Wilcox in Canada.

H. W. WELLER.

Mr. Weller has been an associate member, Institute of Civil Engineers of England, since 1885; he is also a Fellow of the American Institution of Electrical Engineers, a member of the Canadian Mining Institute and past president of the Canadian Association of British Manufacturers.

His clubs are the Constitutional, London; Engineers', Old Colony and Rotary, Montreal. Owing to his part in the early development of the electric railway business he has the honor of being an Edison pioneer.

J. Bartington of the American Locomotive Co. will address the Canadian Railway Club on "Some Recent Developments in Locomotive Construction, Including the Three Cylinder Engine," at the next monthly meeting of the club. The annual dinner will be held Jan. 26.

Elect Canada Council Officers

John Grimshaw Now Worthy Chief of No. 27; Three New Members Initiated

CANADA Council No. 27 Universal Craftsmen Council of Engineers, held a regular meeting Dec. 10, which proved to be one of the best in the annals of the Council, about sixty members being present.

The session was a busy one, starting promptly at 8 p.m. and closing at 11.30 p.m.

The growth of the Council is very gratifying, the following candidates being initiated: Bro. E. Wilkinson, Canadian representative of the Lukenheimer Valve Co., Bro. Beaver, chief engineer of Penmans, Ltd., Paris, Ont., and Bro. A. Fleming, engineer, Imperial Oil Co., making a grand total of one hundred and sixty members.

The nomination and election of officers was an interesting feature of the evening and resulted as follows: Bro. John Grimshaw, worthy chief; Bro. George Jenkins, recording secretary; Bro. H. Parker, financial secretary; Bro. Grand Past Chief H. Terry, treasurer; Bro. W. Bruce, warden; Bro. Alexander Auchterlonie, guard; Bro. George Aldridge, chaplain; Bro. Jas. Miller, trustee.

Regrets were expressed when it was announced that the recording secretary, Bro. Wolfenden, was retiring from office. The efficient manner in which he fulfilled his duties was much appreciated by the council.

An interesting discussion took place relative to the revision of the Boiler Law now before the engineering bodies of Ontario, and Bro. Darbyshire gave an address. Further debate will take place at the January meeting.

Canada Council No. 27 desires to take this opportunity of wishing a merry Christmas and a prosperous New Year to all out of town brothers and readers of Power House.

C. A. S. E. Notes

London No. 30, C.A.S.E., held their regular meeting Dec. 7. The semi-annual report, read by secretary-treasurer J. H. Ward, showed a gradual increase in membership. Mr. Ward is working hard to increase the membership and has many new prospects in sight. A discussion followed the meeting which was beneficial to all present.

T. A. Marsh, A.S.M.E., gave an interesting address under the auspices of Toronto, No 1, C.A.S.E., in the Alhambra Hall, Spadina Ave., Dec. 13, on refractory material ignition arches and their relation to combustion.

Power Notes

The Elliott Co., Pittsburgh, manufacturers of surface and jet condensers, Elliott de-aerators, twin strainers and other steam specialties, have appointed as their Canadian representatives, the Combustion Engineering Corporation, Bank of Hamilton Building, Toronto.

J. P. Porter Co., Hamilton, manufacturers of patent fuel, contemplate the erection of a plant on the C. N. R. property on Burlington St., to cost approximately $100,000. The company proposes to purchase coal screenings, pulverize them and subject them to a process which will extract the ash. The substance is mixed with asphaltic fuel oil and the product formed into a nugget about the size of pea coal. The Canadian company is an off-shoot of the Trent Amalgam Co., of Washington.

The American Steam Pump Co., Battle Creek, Mich., has purchased outright the complete assets of the Advance Pump and Compressor Co., also of Battle Creek. The factories adjoin each other, which feature gives the American Steam Pump Co. an additional unit which it is estimated will increase its production approximately one-third and also give it a larger line of pumps. The Advance plant will be devoted largely to the manufacture of duplex pumps. For the present no changes will be made in the personnel or offices of either organization.

A **150 B. H. P.** Polar Diesel engine has just been installed at the Crown Reserve Mining Company's plant, Larder Lake, Ont. This plant started operations recently.

Two 200 B. H. P. Polar Diesel engines are being installed at the Castle-Trethewey Mines, Gowganda, Ont.

A **75 B. H. P.** Polar Diesel engine is being installed at the New York Porcupine Mines, South Porcupine, Ont.

Representatives of Canada's electrical engineering profession and the hydroelectric industry met at Chateau Laurier, Ottawa, Dec. 7, to discuss Dominion representation at the World Power conference in London next July. A strong committee was appointed to direct the arrangements. It consists of Dr. Charles Camsell, Deputy Minister of Mines; H. G. Acres, Niagara Falls; Arthur Amos, Quebec; John Murphy, Ottawa; Arthur Surveyer, Montreal; J. B. Challies, Ottawa; General Secretary, A. A. Dion, Ottawa; R. J. Durley, Ottawa; J. G. Glassco, Winnipeg; F. R. Glover, Vancouver; A. Monro Grier, K. C., Toronto; B. F. Haanel and O. Higgman, Ottawa; F. S. Keith, O. Lefebvre and Julian Smith, Montreal, and Dean Mitchell, Toronto.

Hon. Charles Stewart, addressing the gathering, stressed the immense power potentialities of Canada, and how scarcity of coal in one province is compensated for by electrical energy in another and vice versa.

An "entertainment" luncheon of the Montreal Electrical Club was held in the Queen's Hotel, Montreal, last week. Every fourth meeting of the club is reserved for entertainment. S. Macnab was chairman, and the meeting was well attended.

Town Council, Bagotville, Que., is in the market for equipment for an electric plant.

Municipality, High River, Alta., contemplate the installation of an additional 75 h.p. unit and equipment for a fuel power plant. S. W. Salt, secretary.

Municipality, Camrose, Alta., contemplate the addition of a 350 h.p. unit and equipment to a power plant. J. D. Saunders, secretary.

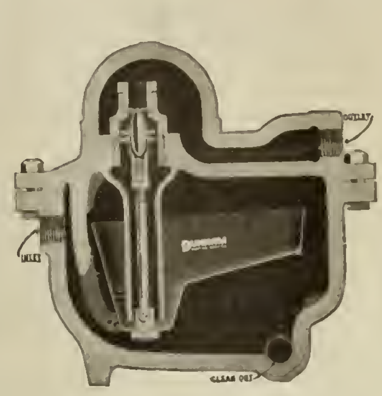
Canada's Fuel Problem 38
Discussion by E.I.C. at St. Catharines.

Dunham High Pressure Bucket Trap—Type No. 80

Quick acting—Powerful—Accessible!



There's nothing "draggy" about the action of this trap. The shape of the Dunham bucket and a short-coupled leverage obtain unusual power and speed. When the bucket is down and the trap is discharging the inclined bottom stands practically in a horizontal position. As the water is forced out through the discharge tube from the bucket, and the bucket begins to rise from the buoyancy of the water surrounding it, all of the water on the bucket "shelf" is suddenly poured over into the water seal. As a result, the movement of the bucket is greatly accelerated in its closing action.

This is a strong, simply constructed trap for removing condensate from fixtures, steam lines, separators, laundry equipment, heaters, vulcanizers, dry kilns and other industrial apparatus where high pressure steam is used. It is the speediest and most powerful trap of its size and type made. This is due mainly to the shape of the Dunham bucket, as described under illustration.

Another big feature is its accessibility. The cap may be removed without disturbing piping connections. This exposes the double-end valve and reversible valve seat which are made of monel metal. These vital working parts may be quickly reversed or replaced. Compare Type 80 with any other trap for operating efficiency and durability.

Write to us to-day for complete information and price list on Dunham Traps and other heating and industrial specialties.

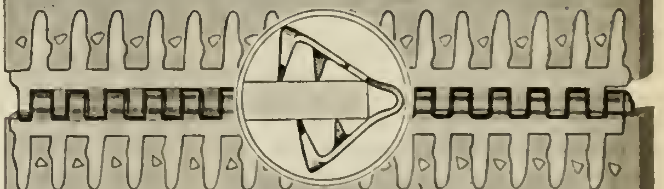
STEEL BELT LACING



For Universal Service

In light machine drives, whether slow, medium or high speed, a joint of Alligator Steel Belt Lacing properly applied is safe and long lasting. Recommended also for heavy drives and for use with idlers, on mule and serpentine drives, flat conveyors, or for tape and extra light drives. It combines the essentials demanded of modern belt joint: strength, smoothness, flexibility and simplicity of application.

A universal joint for universal service—gives universal satisfaction.

Analyze Canada's Fuel Problem

Fifty Members of St. Catharines Branch E. I. C. Study Perplexing Aspects of Present Coal Supply

ABOUT fifty members of the St. Catharines branch of the Engineering Institute of Canada inspected the big power house at Queenston on Dec. 8.

In the evening at the Lafayette Hotel a brief business meeting preceded the main item on the program, namely, "A Symposium on Fuel." The subject was divided into seven sections prepared by members who had made a study of particular aspects of the fuel situation as follows: Pennsylvania Anthracite, by F. S. Lazier, Welland Ship Canal; U. S. Bituminous Coal, by L. B. McDonald, Canada Cement Co.; Canadian Coals, by T. F. Scott, city engineer, Niagara Falls, Ont.; Welsh Coals, by E. P. Johnston, Welland Ship Canal; Coke, by S. R. Frost, American Cynamid Co.; Oil, by J. R. Bond, Niagara Falls, Ont.; Secondary Fuels, by Walter Jackson, H. E. P. O.

Mr. Lazier said that Canada contained 18 per cent. of the coal resources of the world, but it was so placed with respect to Ontario, that the province had to be dependent on Pennsylvania for its fuel.

Mr. McDonald confined his remarks to bituminous slack coal. This fuel was, he said, a by-product of "mine run," of which there was a large surplus on hand until the strike of 1920 made it valuable. Among coals used at the Canada Cement plant, in Port Colborne, in the past few years, was a shipment from Nova Scotia, which Mr. McDonald claimed, was superior to U.S. bituminous.

A description of the lignite found in the Northwest was given by Mr. Scott. While this coal was very cheap, selling at the mines for $1.75 per ton, yet due to its high moisture content, it was not suitable for shipping. The contained moisture dried out in the air in a few hours, leaving a slack which could not be burned in the ordinary furnace. Attempts have been made to briquette it, but without much success as yet, Mr. Scott declared.

Mr. Johnston spoke highly of Welsh coal, anthracite and semi-anthracite, in comparison with other fuels. His figures indicated that Welsh anthracite, costing $19.40 per ton, was about 20 per cent. cheaper than U. S. anthracite at $18.

After a detailed description of the methods used in preparing coke, Mr. Frost claimed coke is as clean a fuel as anthracite and will burn in the same furnace.

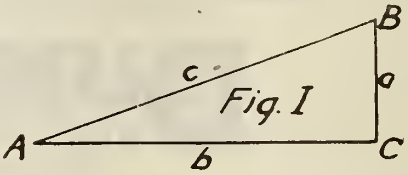
Mr. Bond foresaw the day when oil would find wide use as a heating fuel, claiming the supply is sufficient for hundreds of years.

Mr. Jackson spoke of the relative merits of wood, peat, gas, or electricity, for heating purposes. He did not hold out any hope of relief from any of these materials in the easing of the fuel situation of the province.

SLIDE RULE ACCURACY

In preparing this article the writer has reference to the 20 in. polyphase rule, although the principle is applicable alike to any length rule whether polyphase or not. While the 10 in. rule is commonly used, more so than the 20 in., the former is practically limited to checking, whereas the 20 in. rule can be depended upon almost entirely for accurate figures, if we take advantage of a few "tricks of the trade."

A decided advantage of the polyphase rule is, that with but a very few exceptions, three numbers can be multiplied with but one setting of the slide.



In performing this operation if we have three numbers as, 165 x 917 x 253, it makes no difference which one is taken first, as, if the operation can be performed with one combination, it can be performed with all and the converse is also true.

Still another advantage of the polyphase is, that two numbers may be multiplied and the result divided by a third, with only one movement of the slide. (This also with a few exceptions.) The operations must be performed in the order named, else two movements of the slide will be required.

For Triangulation

The slide rule is used extensively for figuring triangulation and it is with this in mind that the writer offers the following "kinks."

In the triangle A, B, C, Figure 1, let A = 20° and b = 2.6587. Now to find c we have b x secant 20°, which is 2,6587 x 1.0642, and equals as found by long hand, 2.82939. To perform this operation on the rule with the numbers as they stand, we read 2.829, but this is not close enough as many engineers will work to four decimals, except if they are dealing with long distances. Let us think of 1.0642 as 1 + .0642 and express the problem in this form: (2.6587 x 1) + (2.6587 x .0642).

The result of the first quantity is very evident, and multiplying on the rule the figures in the second parenthesis, we obtain .1707. Then 2.6587 + .1707 = 2,8294.

For the accuracy of the result we compare with the long hand figures and note that the error is only .00001.

Referring again to the triangle and supposing we wish to find B having given A = 20° and c = 2.8294. Then b = c x cosine 20°, = 2.8294 x .93969. Now the cosine equals 1 minus versine, therefore if we multiply by the versine instead of the cosine, and subtract the result from the first number, the same final result is obtained.

The problem is then 2.8294 — (2.8294 x .06031). Here again advantage is taken of the decimal point and zero, instead of using such a formidable number as .93969. Multiplying the two numbers in the parenthesis, we read .1707 and subtracting, the result 2.6587 is obtained, the correctness of which is easily seen.

The assistance for accuracy we are able to give ourselves in division, is, for example:

$$\text{Secant A} = \frac{2.8294}{2.6587} = 1.0642$$

2.6587) 2.8294 (1
2.6587
———
1707

The first figure of the quotient, 1, is obtained by actually dividing on paper, and then .1707 divided by 2.6587, on the slide rule, gives the remaining four places, .0642.

The reader having followed thus far will note that by using the slide rule for actually doing most of the figuring, "brain fag" is eliminated to a large degree, and real time saved as well.—CLIFFORD CORNWALL, Toronto.

Obituary

J. Robert Prior, stationary engineer, died at his home, 150 Moy Ave., Windsor, Dec. 5, in his 49th year.

The voltage of a direct-current machine having the same winding as the single-phase alternating-current machine will generate a constant voltage equal to the maximum electromotive force of the alternating-current machine. The effective voltage generated by the alternating-current machine would be only 0.707 times that of the direct-current voltage.

In replacing cylinder head gaskets or valve cages the surfaces should be thoroughly cleansed. Small carbon particles or grit often cause the gaskets to leak.

In a lead storage battery the positive plates are made of lead oxide and the negative plates of sponge lead. The electrolyte is a solution of sulphuric acid and water having a specific gravity of between 1.210 and 1.220 for stationary work and about 1.270 to 1.300 for vehicle and starting and lighting batteries when the battery is fully charged.

PUMPING WATER BY COMPRESSED AIR

(Continued from page 21)

was too large. As it was, a 5-inch water standpipe and a 1½-inch air pipe were in use. A 4-inch water standpipe with special thin pipe couplings was then lowered inside the 5-inch pipe, and the 1½-inch air pipe was discarded in favor of a ¾-inch air pipe.

Demand Continuous

As the demand for water is so continuous and as air at different pressures is needed for various purposes around the plant, a pressure regulating valve was placed in the air line, and this reduced the pressure from 90 pounds to an operating pressure of 45 pounds.

The original installation consisted of a belt-driven air compressor having a piston displacement of 280 cubic feet. This machine has been in operation for twenty years, and is still giving excellent service. In addition, there were two Type EL-1, 8 x 8-inch compressors with short belt drive. One of these machines was removed when the alterations were made and the second one was left for standby purposes only. The present installation is shown in an accompanying picture, and attention is drawn to the automobile engine at the left. This engine was added to the equipment as a precautionary measure in order to guard against a failure of the air supply, inasmuch as a 10-minute interruption would mean the loss of all the ice in process of manufacture. The motor is fitted with a pulley and a long belt, and can be connected to the standby compressor in a very few minutes by simply removing the short belt from the electric motor and substituting the long belt from the gasoline engine.

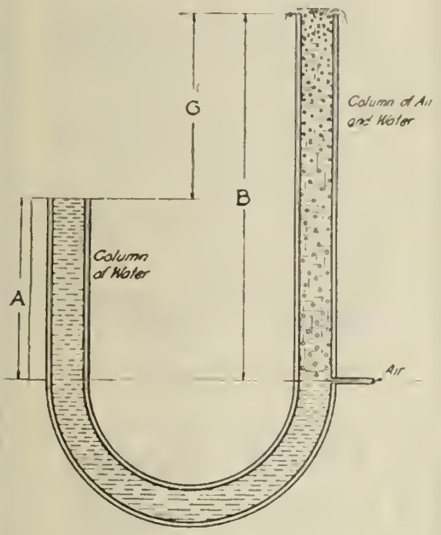


Fig. 1.
The injection of air, at the point indicated, produces a column of mixed air and water "B" which has slightly less weight than the solid column of water "A." Thus the weight of the column "A" causes the water to rise the distance "C" and overflow.

Operates Hoist

Besides using compressed air for pumping water from the well and for agitating the water in the ice cans, it is also utilized to operate a hoist to lift the ice dumped from the cans and to carry it to the daily storage rooms; to convey the ice to the permanent storage rooms; and to operate a direct-lift hoist for harvesting the ice, as shown in one of our illustrations.

In this picture can be seen the air manifold, running along the wall, from which the air is taken for agitating the water while it is undergoing freezing. The pressure reducer is also shown on the wall directly behind the three ice cans. This establishment is interesting not only because compressed air has been put to service wherever possible to operate mechanical labor-saving devices but because it is the first all-Canadian ice-making plant built in Canada.

The saving effected by the air-lift system in this case can be readily appreciated when the added advantages of pure, cold water in an industry of this kind are taken into consideration. In other words, economies are effected through the use of cold water for condensing purposes; through the lower initial temperature and the purity of the water put in the cans for the manufacture of ice; and, lastly, through the pumping of the water itself, which costs less than two cents per 1,000 gallons, as compared with the city water rate of nineteen cents per 1,000 gallons.

POINTERS ON PROPER COMMUTATOR MAINTENANCE

(Continued from page 27)

guided by the opinion of a brush salesman. This gentleman will usually advise their "special abrasive brush made expressly for such conditions." He goes on to state that the abrasive qualities of the brush will grind down the high mica, and your troubles will end as if by magic. He fails to state, however, that the brush will also grind down the copper and very decidedly shorten the life of the commutator.

Locate the Trouble

A man that is really on to his job will seek until he has located the cause of the trouble. Once the cause is found and remedied, sparking will cease permanently.

If it is certain that high mica results from the natural condition of the copper or mica, then undercutting is about the only permanent relief. To do a good job of undercutting requires some knowledge of operating conditions, and quite a bit of patience.

Many different tools and methods have been devised to do the work. The average plant would not be justified in purchasing one of the elaborate electrically driven saw outfits made for this purpose. Occasionally the work can be done in a milling machine. All things considered, the hand method, while taking longer to accomplish the same result, nevertheless often produces a more satisfactory job. A 6-in. slim taper file is the only tool necessary. Break off about ½-in. of the file tip and grind square.

EQUIPMENT FOR SALE

TAYLOR SAFE FOR SALE—INSIDE DIMENsions 15" deep, 2 ft. 6" wide, 3 ft. 11½" high. We will accept $225.00 for this safe—a bargain for someone. Apply Box 110, Power House

For Quick Sale

Self-oiling high speed engine, single cylinder 17 in. bore x 16 in. stroke. Engine develops 200 H.P. when running at 235 R.P.M. with 100 lbs. steam pressure. There are two heavy leather belts 18 in. wide. The engine has two fly-wheels, each 78 in. diameter x 18 in. face. Apply Box 112, Power House.

PISTON RINGS

EVER-TYTE and ZELCO Piston Rings with Patented Zelco Process Save Gasoline, Oil, Increase Capacity, Prevent Cylinder from Wearing Out of Round, Lessen Carbon; after using, make arrangement with us to sell them; made up to 80-inch; used in Locomotives, Boats, Engines, Compressors, Ice Machines, Autos, Trucks, Tractors, etc.; are looking for distributors with mechanical knowledge; all or part time; real opportunity. Ever-Tyte, St. Louis, Mo.

When answering advertisements, please mention POWER HOUSE

Hold the file at a slight angle to the commutator surface.

Keep Slots Shallow

Start the file at the end of the mica segment and work back towards the armature core, keeping in the centre of the mica. The square end of the file will act as a sort of plough. Remove the mica to a depth of about 1-32 in. The shallower the slots, the easier to keep clean and free from accumulations of carbon dust and grit. Be sure that the entire width of the mica is removed. A thin sliver left flush with the surface of the copper will often defeat the purpose of undercutting. All sharp edges should be removed from the copper bars.

One precaution to be taken with undercut commutators is that oil should not be permitted to work on to the commutator. Oil and carbon dust will clog the slots and cause endless trouble.

A hard, non-abrasive carbon brush will give good results when undercutting is resorted to. Brush tension can also be reduced considerably. Usually 1½ lb. per sq. in. of cross-section is sufficient.

WHAT USUALLY CAUSES THE SCORING OF A JOURNAL

(Continued from Page 26)

the engine round certain portions of the stroke, under a very early cut off. The only remedy for this is close attention.

If in spite of the vigilance of the engineer, or because of lack of it, scoring of a journal does actually occur, the writer would suggest the following remedies. First, do not waste time and avoirdupois trying to get the score out with a piece of canvas. If the scoring warrants it, and it is possible, send the job to a shop, and have the journal turned up, or have the grooves filled by electric welding, and the journal smoothed up in the lathe.

If this cannot be done, get a good second cut file and a pair of calipers. File carefully with a half round motion, going round the journal evenly, and trying with the calipers frequently to see that the journal isn't being made oval. When the surface is reasonably good, finish up with a smooth file, and emery paper. If a really good job is desired use last of all an oil stone.

Then set up the bearing in the proper way, and look after it in future.

A FLOATING DRIVE

We had to get a boring fixture at work in a hurry and there wasn't a floating joint to be had in the place. So the foreman told us to wrap a layer of heavy wrapping paper around the taper shank of the tool, put it in the socket and drill through for a drive pin.

Then we took off the paper, put the next sized larger drill through the holes we'd drilled in the socket, used a pin that was a light drive fit in the shank, and we had a drive with just a little "float," which was what we wanted. And we made it in a hurry, too.—A. SMYTH.

MONCRIEFF'S "UNIFIC" WATER GAUGE GLASSES

Moncrieff's "Unific" is not a cheap glass. But because it outlasts many ordinary glasses the "Unific" is **economical.** British Made.

The "Unific" does not readily corrode. It resists extreme changes of temperature and withstands the highest working steam pressure.

Removing Scale from Return Tubular Boilers.

Phone Adel. 1135.
Day and Night Service.

Write or Phone for full particulars.

SIX REASONS WHY

You should give the Dean Boiler Tube Cleaner a Trial in your own Boiler and see what it will save YOU.

1. We will give you a demonstration FREE showing you the conditions of any Boiler.
2. We guarantee to save you from 20% to 50% of your fuel.
3. Is recommended by both Boiler Makers and Inspectors.
4. 90% cheaper to clean old ones than to retube with new.
. A clean Boiler is 50% safer, more efficient and economical, than one covered with Scale, if only 1-16 thick.
6. We will send you a Dean on Trial in one Boiler FREE

OR CLEAN YOUR BOILERS OF SCALE BY CONTRACT.

Geo. Farrow & Son, 17-19 Victoria Blvd., Mount Dennis, Toronto

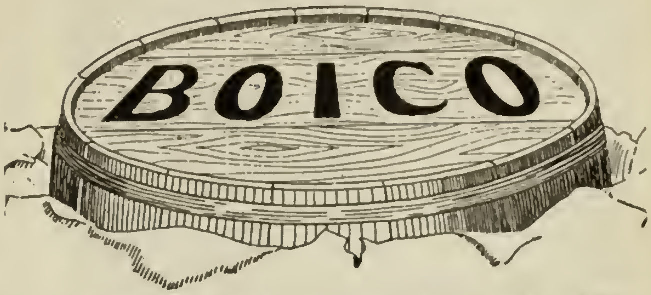
Makes Short Work of Boiler Scale

In hundreds of plants BOICO has been adopted as the one sure clean-boiler insurance. The speed with which it removes the most stubborn scale formations is surprising. Hurts nothing but boiler scale. It's economical, too.

TRY IT FREE—let us send you a sample to convince you. Write us to-day—you've nothing to lose.

SHELL-BAR BOICO SUPPLY LTD.
1-15 SAUNDERS AVE. - TORONTO



SALES AGENTS: Mill Supply Department, Beveridge Supply Co., Ltd., Montreal; Adolphe Huot Reg'd., Quebec; Adam Davis, Cobalt, Ontario.

Why Individual Boiler Feed Water Treatment

Because the Condition of Each Individual Boiler Differs

We have demonstrated it to be the most successful method of freeing boilers of scale and stopping the further formation of scale-forming deposits or incrustations. Corrosion or pitting stopped at once by our scientific process which accomplishes the results desired.

"CLEAN ALL"

Indicates in a few words what the process does.

The Allen Feed Water Purifier Co., Limited (Sole Makers)
Distributors: William C. Wilson & Co., 21 Camden Street, Toronto

MIDWEST CANADA LIMITED
83 CRAIG ST., WEST MONTREAL, QUE.

"99 44/100 % Pure"

After testing out ordinary boiler feed water regulators in direct comparison with COPES, Procter & Gamble Company have placed another repeat order for 18 more Copes.

N. K. Fairbanks & Co., Colgate & Co., and the Larkin Co., Inc., also use COPES.

The highest standards of power plant efficiency are maintained at these great plants. So they use the boiler feed control that is

99 4/5% Accurate

24-hour tests which have been made, in actual service, show that the COPES gives smooth feeding that is accurate to 1/5 of one per cent.

The savings in fuel and labor, directly due to the accurate and reliable feeding of the COPES, pays back the cost of installation over and over again. Write for Catalog D, giving the facts.

SYSTEM OF BOILER FEED CONTROL

TRIPLEX DRAFT GAUGE

Gives you accurate knowledge of furnace conditions at a glance. It indicates pressure in wind box, draft in furnace above the fire and draft in last pass.

It is designed and built for convenience of installation, maximum visibility and permanent accuracy. Each instrument must pass the Foxboro quality test.

Write for Bulletin CF-131.

Removes Every Drop of Water

LOSSES amounting to thousands of dollars each year, as well as many serious accidents, are caused where condensation is not properly drained from coils, pipe lines, separators or other apparatus.

Steam traps of many designs are used to remove the condensation. To be efficient they must remove all the water and discharge it as fast as it condenses. They too must avoid any discharge of steam pressure. This is exactly what the Fisher Steam Trap is designed to accomplish—and what it is accomplishing in the many plants where it is installed.

If your present trap is not in every detail satisfactory, you will make no mistake in installing a Fisher Trap.

Fisher Features

The Fisher Trap has many superior features. Valve seats can be changed instantly without disturbing pipe connections. Has intermittent discharge, eliminating wire drawing of valve seat. All parts extra heavy. Float made of cast iron, open bucket type, which is trouble proof. Lifts condensation two feet to each one pound pressure on the trap. It has many other features, too, in which you will be interested. Write for complete description.

Still Going Strong

This pump was put in here fifteen years ago, and with no more than ordinary attention is still good for years to come.

There are many pumps made by Smart-Turner Machine Company that are older than this. Have you one?

The first pumps made by Smart-Turner Machine Company were built nearly a quarter of a century ago, and the records of the earliest manufacture have been destroyed.

If you have a Smart-Turner pump older than the one above, please write us, giving date of installation.

Are You Wasting Fuel?

Numerous Canadian power plant men correctly answer that question by using the HAYS IMPROVED GAS ANALYZER. Rugged, portable, fast, accurate and INEXPENSIVE, it is the acknowledged leader of Flue Gas Analysis Instruments. Made in two styles. 3-chamber Analyzer for CO_2, O_2 and CO; 1-chamber Analyzer for CO_2 only. Stocked by Canadian Agents listed below.

Hays Improved Gas Analyzer.

HAYS DRAFT GAGES, "the fireman's compass," tell him how to regulate his damper, the condition of fires, baffles and settings. Write for your FREE copy of Jos. W. Hays' Treatise on "Drafts and Draft Regulation."

Stephen's Boiler Feedwater Treatment

Don't endanger your boilers with old-fashioned, expensive methods which are often ineffective. You'll find that the Stephen's Feedwater Treatment is not only more economical but ensures the removal of old scale and prevents the formation of new scale in absolute safety.

Consult our engineers. They are always happy to discuss your feedwater problems in a practical way without obligation to you.

Stephen's Chemical Mfg. Co., Ltd., 2 Johnston St., Toronto, Canada

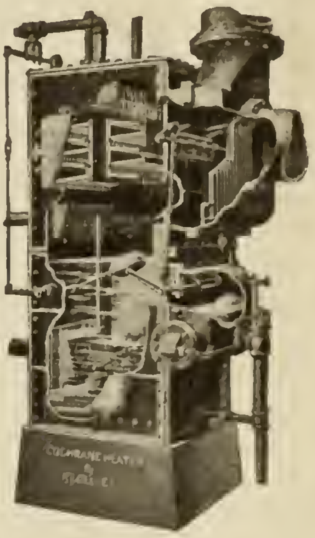
Increase Your Business By Reducing Production Costs

Locate, and thru the COCHRANE METHOD Stem the Tide of Waste in your Steam Power Plant

HEATING boiler feed water by means of exhaust steam effects a very considerable saving in fuel. The heat imparted to the water in the feed-water heater takes the place of an equivalent amount of heat from fuel on grates. If the water is heated from 60° to 210° F., the fuel saving amounts to approximately 14%, or 1% of fuel is saved for each 11° F. rise in the temperature of the water.

The importance of having the right kind of feed-water heater is shown by the fact that a difference of 1, 2, or 3% of the yearly fuel bill will, in most cases, cover the entire cost of a heater of any type.

The use of exhaust steam for heating the boiler feed water adds to the boiler steaming capacity; since, as part of the heat is supplied to the water in the heater, the boiler is able to make more steam with a given amount of heat supplied by the fuel. Roughly, six boilers and a Cochrane Heater will make as much steam with less fuel and labor, as seven boilers without a heater.



Cochrane Steam Stack and Cutout Valve Heater
